Professor of Medicine, Medical College, Calcutta

MANY of the salmonella organisms have been from time to time reported to give rise to disease in man. An editorial, *British Medical Journal* (1945), divides human salmonella infections into three clinical varieties, viz, paratyphoid fever, salmonella septicæmia and salmonella food poisoning. Bornstein (1943) holds almost the same view. Another editorial in the *British Medical Journal* (1946) comments: 'The septicæmic type of infection with salmonella strains appears to be on the increase in this country and this increase seems to be even more marked in India'. The literature in India about the description of various salmonella infections as diagnosed by isolation of the organism is scanty. Whatever there is refers mainly to the paratyphoid fever in the majority of cases due to *B. paratyphosum A*. Most of these reports are however confined to their incidence without any reference to their clinical features. Karunakaran and Pillai (1942) described 9 cases in 2 family outbreaks

of fever due to *B. paratyphosum A*. Wasti (1945) only recently has published the description of 9 cases of *B. paratyphosum C* fever where, with one exception, the diagnosis was made by isolation of the organism. Goyle and Shaikh (1943) described one case of enteric fever in a child due to *B. enteritidis*. This appears to us as the first published record in India of the invasive property of *B. enteritidis*. McDonald (quoted by Hayes and Freeman, 1945) described, in 1944, 3 cases of septicæmia caused by *B. enteritidis* occurring among Indian troops. *B. paratyphosum B* has received very little attention except an occasional passing reference to its rare incidence. Thus, Seshadrinathan and Pai (1940) isolated *B. paratyphosum B* from 3 cases. Karunakaran and Pillai isolated it from the stool of a patient from whose blood *B. typhosum* was grown. Minehin (1939) got 2 cases of *B. paratyphosum B* but he did not mention whether the diagnosis was based on culture or agglutination reaction. Hayes and Freeman (1945) isolated it only 7 times in a series of 548 salmonella infections.

In our series table I and the following account summarize the clinical and related features of 10 cases of *B. paratyphosum A*, 6 cases of *B. paratyphosum B*, 15 cases of *B. paratyphosum C* and 12 of *B. enteritidis*. In all these cases the corresponding salmonella has been isolated from the blood with the exception of one *B. paratyphosum C* which was isolated only from the stool and another of *B. enteritidis* that was isolated only from the pus.

Bact. paratyphosum A

Altogether 10 cases have been studied. Of these, 4 ran an uncomplicated course lasting from 9 to 15 days. Toxæmia was slight. Maximum temperature was 103°F. One case came with all the signs and symptoms of typical pneumonia.

TABLE I

Only tympanitis and caecal gurgling were very prominent in this case. The temperature was controlled by the administration of M. & B. 693 on the 9th day. In 2 cases fever lasted up to the end of the 3rd week. Another had a peculiar course in that the temperature was remittent up to the 5th day and then continued intermittently up to the 40th day, the highest temperature in these 3 cases being 103°F. The other 2 cases which became fatal were cases of relapse after an apyrexial period of 2 days. Both had pulmonary complications, viz, bronchitis and right lobar pneumonia respectively in their primary course. During the relapse, one developed bronchopneumonia and the other lobar pneumonia again. The primary fever in both was of longer duration, viz, 25 and 33 days respectively. It is curious that both of them died on the 19th day of relapse.

Other features.—Constipation in 4 cases. Diarrhoea in 3 cases. Cough in 3 cases apart from the 3 who developed pneumonia. Bradycardia in 4 cases. Spleen was enlarged in 8 cases and liver in 4. Rose spots were noted in one case on the 11th day of the disease.

Blood examination :—

	TOTAL LEUCOCYTE COUNT PER C.M.M. OF BLOOD			
	Below 5,000	Between 5,001-7,000	Between 7,001-10,000	Above 10,000
Number of cases.	1	3	3	3

Blood culture.—Positive in the 1st week—3 cases; positive in the 2nd week—6 cases; positive in the 3rd week—one case only.

Agglutination reaction.—In 4 cases it was positive to AH; 1 in 50 in 2 and 1 in 83 in 2. The days of illness in which such positive reaction was obtained were 7, 11, 15, 17. The sera of 3 of these positive cases were also positive either to BO or TO and BO in 1 in 25 dilution. The remaining cases were all negative to TH, TO, AH, BH and BO in all dilutions.

Bact. paratyphosum B

Altogether 6 cases have been studied. Four cases died on the 8th, 9th, 12th and 13th days respectively. All these had high fever (103°F. to 105°F.) with marked toxæmia and stuporose condition which were followed by typical typhoid state and death. The first case developed bronchopneumonia over which circulatory failure supervened and carried away the patient. The second case was afebrile for one day only, death occurring from acute cardiac failure. The third case was interesting in that the temperature was typically septicæmic in type with daily intermissions and evening rise to 103°F. to 104°F. The fourth case followed a

classical enteric course, death occurring from toxæmia and circulatory failure. The other 2 cases were of short duration, 12 days in one and a little over two weeks in the other.

Other features.—Diarrhoea in 2 cases; constipation in 2; bradycardia in 1. Liver was palpable in 3 and spleen in 5. No rose spots were seen in any one.

Blood changes.—Leucocytes—between 5,000 to 7,000 per c.mm. in 2; 7,001 to 10,000 in 3; above 10,000 in 1.

Blood culture.—Positive in the first week in 2 and in the second week in 4 cases.

Agglutination reactions.—BH was positive in one case on the 7th day, to a dilution of 1 in 125. BH and BO were negative in 5 cases but of these cases TH and TO were positive 1 in 50 in one and, in another, TH was positive 1 in 25 only.

Bact. paratyphosum C

Fifteen cases have been studied of which 6 were fatal. Two cases died of perforation. One of these had diarrhoea at the beginning, perforation having occurred on the 18th day. The other developed diarrhoea during the course and died of perforation on the 32nd day. Two cases died of severe toxæmia and circulatory failure on the 11th and 13th days. Two others had pulmonary complications. Nine cases survived. In one of these cases, the termination of the enteric fever could not be defined owing to the development of pleural effusion. All the 6 cases which continued their course beyond the second week had severe toxæmia. The rest finished their course within two weeks and did not show marked toxæmia. The temperature, in all the cases, was of a continuous or remittent type, the highest varying between 103°F. and 105°F. One case had hyperpyrexia, the fever shooting up to 106°F.

Other features.—Three had onset with chill and rigor; 3 had constipation and 2 diarrhoea. Pulmonary involvement was found in 3 cases; bleeding from the gums in one case, epistaxis in 1 and bradycardia in 1. Liver was enlarged in 5 cases and spleen in 11. Rose spots appeared in one case on the 16th day of the disease. Complications were frequent. Besides bronchitis and bronchopneumonia, hæmorrhage occurred in 1 and perforation in 2 cases both of which terminated fatally. One developed a nervous complication characterized by slurring speech and paresis of both the limbs, these conditions being progressive during convalescence. He had also suppuration in the right thigh at the site of an injection. One other case was complicated by pleural effusion.

Blood changes.—Leucocytes—below 5,000 per c.mm. in 3 cases; between 5,001 to 7,000 in 6 cases; 7,001 to 10,000 in 4 cases and above 10,000 in 1. One case showed progressive leucopenia from 9,680 to 4,375 per c.mm. on the 18th day.

Culture.—Positive in the first week in 2 cases and in the second week in 13 cases. In one of these cases, *B. paratyphosum C* was isolated twice from the blood. In the case in which nervous manifestations and suppuration took place, the organism could be isolated from the blood on the 9th day, urine on the 30th day, stool on the 42nd day and from the pus on the 45th day of the illness. In another case, the organism was isolated from the diarrhoeic stool only.

Agglutination reaction.—In 3 cases it was positive to CH only, 1 in 50 on the 15th day, 1 in 250 on the 19th day and in the 3rd case 1 in 250 on the 32nd day. In 2 cases, the serum reactions were all negative on the 9th day but later on TH became positive in one, 1 in 125 on the 16th day and in another 1 in 250 on the 31st day. Other cases were negative to all.

B. enteritidis

Altogether 12 cases have been studied and of these 6 were fatal. All the patients had continuous fever and marked toxæmia often merging into coma and delirium. The 6 fatal cases died on the 13th, 9th, 7th, 15th, 12th and 7th day respectively. The first of these cases died of toxæmia and circulatory failure. The next 2 cases were complicated by hyperpyrexia which could not be controlled. One of these latter had severe epistaxis and bouts of hæmoptysis before death.

The 4th case was associated with severe anaemia, the hæmoglobin being less than 30 per cent or 4.26 gm. per cent. The 5th case was complicated by pneumonia while the last one which had splenomegaly with positive aldehyde and Chopra's test developed fatal bronchopneumonia. In 4 cases which recovered fever was not of long duration, having lasted for 9, 9, 11, and 12 days respectively, although the height of the temperature and toxæmia were comparable to those of the more severe cases. Only one of these showed signs of pulmonary involvement. In one case the temperature and duration of the illness were like those of typical

typhoid fever. While convalescing this patient developed bilateral gluteal abscess. The pus from these contained *B. enteritidis*. In the last case, after a course of continuous fever for 10 days, the temperature touched normal. This was subsequently followed by irregular intermittent fever up to the 37th day. It was found that the patient had developed an abscess in the right gluteal region at the site of a quinine injection which was given to him before he came into the hospital. The diagnosis of this case was based on the isolation of the causative organism only from the pus.

Other features.—Constipation in 5 cases; diarrhoea in 1; bradycardia in 5; enlargement of the liver in 9 and that of the spleen in 10 cases.

Blood changes.—Leucocytes—below 5,000 per c.mm. in 1 case; between 5,001 to 7,000 in 7; 7,001 to 10,000 in 3 cases.

Culture.—Eight cases were positive in the first week, 2 in the second week and 1 in the third week.

Agglutination reaction.—Eight cases were negative to the group. The blood serum of one case, which was negative on the 17th day, became positive to TO on the 24th day in 1 in 125 dilution. In another case, the serum though positive to TO on the 7th day in 1 in 83 dilution, was negative to *B. enteritidis*. In two other cases, the serum agglutinated with TO, TH and AH in varying titres but failed to show any reaction with *B. enteritidis*.

Table II and the graph compare the monthly incidences of *B. typhosum* and the various salmonellas during the three-year period 1943 to 1945. It may be noted that while the latter were distributed more or less uniformly throughout the year, *B. typhosum* showed a definite seasonal rise with its peak in August.

Table III shows the number of cases from which *B. typhosum* and other salmonellas were isolated in the Calcutta Medical College Hospitals during the two five-year periods between 1936 to 1946 and the percentage incidences of *B. typhosum* and *B. paratyphosum A*. It also compares the corresponding figures as

TABLE II

collected from the reports of observers all over India.

Table IV gives a more detailed account of the typhoid-salmonella organisms isolated in the Calcutta Medical College Hospitals since 1936.

It will appear that the figures in table I are often smaller than the corresponding figures in tables II, III and IV. This is due to the fact that only those cases whose clinical details were available have been selected for study and entered in table I.

Discussion

The cases described above had all been admitted into the Medical College Hospitals, Calcutta, with fever as their main complaint. The organisms were mostly isolated from the peripheral blood showing their invasive nature. There is a lingering belief amongst the profession that some members of the group are usually associated with acute bacterial food poisoning, that pathologically they remain localized to the intestinal tracts, that clinically there is acute gastro-enteritis with either clinical and bacteriological cure or death in a few days, and that epidemiologically they cause outbreaks in the majority of which infected animal food serves to convey the infection. It is also

believed that next to *B. typhosum*, *B. paratyphosum A* produces more bacteraemia and general symptoms of fever and toxæmia whereas the *B. paratyphosum B* and *C* and *Bacillus enteritidis* produce less general reaction but more symptoms of localized infections, viz, nausea, vomiting and diarrhoea. In other words, the invasiveness of these organisms progressively diminishes as we come downwards from *B. typhosum* and it is likely to be the least in *Bacillus enteritidis*. From a study of our 43 cases, it will be apparent that the causative salmonella organisms instead of confining themselves and their activities to the intestinal tracts have become definitely invasive and found their way into the blood stream causing bacteraemia and toxæmia. It is obvious that the intestinal wall has failed to stop the aggression of the bacteria and their setting up of inside bases from which bacterial showers are constantly thrown into the circulation. When such showers are intermittent, the clinical picture is dominated by an irregular up and down temperature with toxæmia and resembles a septic fever. But when the bacteria flow into the circulation steadily and continuously, the clinical picture resembles a remittent or continuous temperature with varying degree of toxæmia as one may see in a severe case of typhoid fever. Only one of our cases conformed to the typical septic type. This was a case of *B. paratyphosum B*-infection in a young, otherwise healthy student, aged 21 years, showing typical septic type of intermittent fever with all the features of grave toxæmia. As far as we can gather, such a manifestation has not been reported with *B. paratyphosum B* infection but has been known in cases of *B. enteritidis* (Guthrie and Montgomery, 1939, also McDonald quoted by Hayes and Freeman, 1945). In the present series of cases, however, the writers could not find any septic type of fever in any of the 12 cases of *B. enteritidis* infection.

About the *B. paratyphosum A* infection, the most conspicuous feature is its mildness and its short duration in 50 per cent of the cases. The two fatal cases had both long primary fever followed by relapse and accompanied by grave pulmonary complications. In this connection, it is interesting to note that Karunakaran and Pillai (1942) reported no death among their 10 cases, nor did Goyle and Shaikh (1946) out of the 35 cases reported by them. When we come to *B. paratyphosum B* infection, the picture is reversed. Toxæmia and severity of symptoms were marked in most of the cases. In 17 cases reported by Parry (1942) diarrhoea was a prominent feature in 10. Topley and Wilson (1936) remark that *B. paratyphosum B* may excite marked gastro-enteritis during the course of the fever it produces. Hayes and Freeman (1945) quote Savage and also Feemster and Anderson to say that *B. paratyphosum B* infection may manifest itself as pure gastro-enteritis. No such features could be found by the writers

in their cases. *B. paratyphosum C* infection, contrary to the usual teaching of textbooks, is not so innocent. In the present series of 15 cases, only 3 were of short duration and associated with mild toxæmia but this fact is more than counterbalanced by 6 deaths, long duration and severity of toxæmia in the remaining cases and by the frequency and variety of complications, the most remarkable being perforation in 2 cases and progressive paralysis during convalescence in another. Wasti (1945) described 9 cases with 3 deaths. Complications were bronchopneumonia, M.T. malaria and arthritis. In his review of the literature *B. paratyphosum C* was found to have a marked suppurative tendency which however he did not meet with in any of his own cases. In the series under discussion, one developed an abscess from which the organisms were isolated.

All the cases of *B. enteritidis* infection were characterized by severe toxæmia regardless of the duration of the disease. Complications were hyperpyrexia in 2 cases, severe epistaxis and hæmoptysis in one and pneumonia in another. Hayes and Freeman (1945) contend that *B. enteritidis* septicaemia often culminates in suppuration. Gluteal suppuration developed in two out of our 12 cases while in the convalescent stage and another case (not included in the series, as full details of the case could not be obtained) admitted as enteric fever showed the organism in a sample of pus obtained from an abscess which had developed over the sternal region. Another feature is that though *B. enteritidis* is one of the classical organisms for acute gastro-enterocolitis, in none of our 12 cases of invasive type was there any indication of such symptoms. Only one had diarrhoea but as a symptom it has been found to be more common with the *B. typhosum* and other salmonella infection. It appears that the bacterium which is a true salmonella has during its process of evolution undergone complete mutation while acquiring the faculty of invading the blood stream and the body organs.

Widal reaction and blood culture.—In all our cases, diagnosis was based on isolation of the organisms, in one case from the stool, in another from pus and in the rest from the blood. In nearly 60 per cent of the cases, the blood culture was positive in the second week and in more than 4 per cent it was positive in the third week. This shows that we should not neglect blood culture in a suspected enteric case even though the disease has passed beyond the first week. The superiority of blood culture over the Widal reaction and in fact its indispensability is further proved by the fact that if we were left to diagnose the nature of the enteric fever by Widal reaction alone with the usual TAB suspensions we would have missed or misdiagnosed most of our cases. Many of the cases showed non-specific agglutinins even up to a considerably high titre. Although the possibility of mixed infection was there, they indicate the

difficulty of proper interpretation of the Widal reaction in these cases. Some of the enteritidis cases showed TO positive and TH negative. McDonald (quoted by Hayes and Freeman, 1945) also found 2 out of his 3 septicæmic cases positive to TO. Unless this possibility due to sharing of the same somatic antigen by *B. typhosum* and *B. enteritidis* is specially remembered, the cases are likely to pass off, in the absence of blood culture, as infection with *B. typhosum* where the flagellar antibody has failed to develop.

From the above it may be noted that many of the pyrexias seen in the hospital and also outside which run their course for more than a week and which resemble typhoid fever clinically may be due to salmonella infection. The routine agglutination reaction against the classical TAB may be negative in these cases. If careful blood culture is done, the causative organism may be isolated and the true nature of the fever may then be ascertained. In this way the incidence of such salmonella fevers would certainly be much higher than what is indicated in this paper.

It may be noted that the prognosis of salmonella infection is not always very favourable. Savage (1942) while studying the epidemiological features of 40 British outbreaks due to *B. para B* recorded a case mortality of 1.76 per cent. It has also been stated that the prognosis is worse in war time. Frazer, Glover and Glass (1937) recorded an outbreak of 123 cases of paratyphoid B fever with 11 deaths, i.e. 9 per cent in Liverpool. In our series the case mortality is very high.

the organism has been isolated here more frequently, nevertheless we agree with all the other observers that it is the least common salmonella in India. It has been seen even less frequently than the two new-comers in Calcutta, we mean *B. paratyphosum C* and *B. enteritidis*. About these latter organisms, it may be noted that although none was recorded in Calcutta before 1942 their incidence was found to be fairly steady since 1942 onwards (*vide* table IV). From this table one may also see that *B. paratyphosum C* made its first appearance in 1942, and from the next year its incidence remains at a fairly constant level till July 1946. In 1943, *B. paratyphosum C* was isolated even more frequently than *B. paratyphosum A*. One may remember that this was the time when the Burma evacuees began to pour in. From the next year *B. paratyphosum C* became almost endemic, the infection being maintained steadily probably through new carriers existing amongst these refugees. Hayes and Freeman (1945) also remark 'the movements of civilian population following Japanese invasion of Burma may have played a part in its introduction'. Wasti (1945) on the other hand refers to the detection of many sporadic cases of *B. paratyphosum C* infection among civilian labourers hailing from Bengal, Madras and Nepal, suggesting that these men were exporting the infection. Unfortunately, the times of these isolations are not definitely known. It is more probable that they contracted the infection primarily from the Burma evacuees on the way. Hayes and Freeman (1945) suggest that this infection might have been introduced into India by Chinese personnel.

	<i>B. para A</i>	<i>B. para B</i>	<i>B. para C</i>	<i>B. enteritidis</i>	All salmonellas
Number of cases ..	10	6	15	12	43
Number of deaths ..	2	4	6	6	18
Percentage of case mortality ..	20	66	40	50	42

It is difficult to explain satisfactorily the cause of this unusually high mortality. But the general ill health of the patients in the tropics, their poor resisting power and the delay in their hospitalization may all be contributory factors. Of course the number of cases in this series is very small.

A reference to table III will show the frequency of isolation of the various enteric organisms as recorded by different observers all over India. Lakin (1937) and Manson-Bahr (1945) stated that *B. paratyphosum A* was the commonest cause of enteric fever in India. But all the above figures unanimously repudiate their suggestions about such an incidence. From a further study of the above table, it will be evident that the incidence of *B. paratyphosum A* infection not only varies in different parts of India but also in the same region from year to year. Regarding *B. paratyphosum B*, although

Regarding *B. enteritidis*, a more definite origin may be suggested. The first report of this infection was made by Goyle and Shaikh (1943), the patient being a Burma evacuee. This fact may serve as a proof that *B. enteritidis* infection in Calcutta is a Burma supply, this great city being the chief receiving base for all Burma refugees. Hayes and Freeman (1945) have also received the bulk of their enteritidis strains from Calcutta. In this connection it would be highly illuminating to know the incidence of *B. enteritidis* and *B. para C* infection in Burma. We should not however lose sight of other possibilities. Animal sources might have spread the infection in Calcutta. Ghosal (1941) isolated *B. enteritidis* from 32 rats in Calcutta out of 364 he examined. Meagre hygienic sense among people, closer contact between rats and men, specially due to overcrowding during the Japanese war, with or without a rise in the

infection rate among the rats, might all have played their parts in this connection. *B. paratyphosum C* has, however, refused any animal host so far, being unique in this respect amongst the salmonellas, so that human cases and carriers are the only sources of the infection.

Summary and conclusions

1. Forty-three cases of salmonella fevers have been studied. Except 2 cases, the diagnosis has been established by isolation of the causative organism from the blood.

2. Clinical features including haematological and serological changes have been briefly stated. It has been shown that salmonella fevers are by no means always mild in their course; nor are they attended with a low mortality.

3. The incidence of the various types of salmonella organism in Calcutta as well as in other parts of India has been discussed.

4. The probable causative factors responsible for the heavy incidence of *B. para C* and *B. enteritidis* in recent years have been suggested.

The writers take this opportunity of offering their thanks to the Superintendent, Medical College Hospitals, for his permission to publish the records of the cases.

A TECHNIQUE FOR THE TREATMENT OF NAGA SORES WITH PENICILLIN

By MARY WHITESTONE, M.B., B.S. (Lond.)
 Medical Officer, S. Luke's Hospital, Chabua, Assam

TROPICAL ulcers, known locally as Naga sores, were carried into the plains of Assam in 1942 by refugees from Burma and by labour forces returning from work on the refugee routes; since then they have become a scourge among both villagers and tea-garden labour forces. All kinds of treatment for septic surfaces have been tried with varying success, but the majority of ulcers are very resistant to treatment, in consequence of which a number of cases used to discharge themselves unhealed as they grew impatient at such slow progress: some cases needed amputation as a life-saving measure.

Penicillin has recently been used as a local application for Naga sores and quickly eradicates the infection; the ulcers usually become painless during the first 24 hours, and a healthy surface on which grafts can be laid is quickly obtained.

The following is a comparison between 35 cases treated with penicillin and 35 cases treated before penicillin came into use:—

	With penicillin	Without penicillin
Average number of days in hospital.	23.1	34.2
Healed or nearly healed on discharge.	33	21
Improved	2	6
Unrelieved	7
Amputated	1

Although the average number of days in hospital is still high, this form of treatment constitutes the only real improvement obtained in this hospital since Naga sores were first treated in 1942. The great advantage from the patient's point of view is that the ulcer, which used to remain extremely painful throughout the many days of treatment, is usually made painless within 24 hours. The cost of penicillin is now very much reduced and with careful and economical use the treatment of large numbers of patients can be carried out at very little cost. The technique of dressings described below has been developed with the idea of making the most of each phial of penicillin:—

1. A phial of penicillin is made up with 10 c.c. of water and kept in the refrigerator.
2. Of this, on the first day, a small amount is taken and diluted with water to give 500 units per c.c. (i.e. 1/40 dilution for a phial of 200,000 units).
3. The ulcer is thoroughly cleaned with soft rag or gauze until no more of the slough can be removed: this is important and may require morphia in order to do it thoroughly.

4. Two or three layers of gauze cut to the size of the ulcer are laid on it and soaked with the solution by means of a dropper. If the ulcer is deep or undermined, 2 or 3 drops are put directly onto its surface before applying the gauze.

5. The gauze is covered with rubber tissue, then with more rag or gauze to absorb the pus, and the whole bandaged.

6. All ulcers on the foot or leg are treated strictly in bed.

7. A splint is used for all ulcers on mobile parts such as fingers, dorsum of the foot, ankle region, etc.

8. The dressing is repeated after 24 hours. To allow for deterioration in the penicillin the concentration of the solution used for dressing is doubled on each successive day on which the same phial is used. In view of recent reports on the stability of penicillin it seems that the concentration need not be increased nearly so rapidly and I propose in future not to double the strength of the solution until the fourth day of use.

9. The daily dressing is continued until no slough adheres to the ulcer base when the dressing is removed, leaving healthy granulations. A thin watery pus can safely be ignored.

10. After-treatment consists of grafting any ulcer over about $1\frac{1}{4}$ inches in size. (In the above series of cases all such ulcers were not grafted as permission was not always obtained.) Pinch grafts under local anaesthesia in the ward are suitable for all but the very large ulcers. If grafts are not used any mild antiseptic dressing can be applied until epithelialization is complete.

11. If tendons are involved the infection may be difficult to eradicate owing to the impossibility of bringing the solution into contact with the whole of the infected area: until such tendons slough away there is a focus from which infection may respread if penicillin is abandoned. This may be overcome by:—

(a) Excision of the ulcer—a formidable operation once tendons have been involved.

(b) Parenteral penicillin—an extravagant form of treatment: this was used in two cases of the above series: in one it was used experimentally to compare its effect with that of local application and a soda sulphate solution was used locally; the slough appeared to be no thinner after 24 hours and injections were abandoned in favour of local penicillin which had its usual rapid effect. In the second case injections were used in conjunction with local penicillin on account of the depth and severity of the infection: the result was a dramatic improvement. In my opinion this combined treatment should be reserved for those cases in which the infection is spreading in the deep tissues: this spread is accompanied by marked toxicity and high fever which are rapidly brought under control.

(c) Continuing the penicillin dressing until the whole ulcer is clean—this has the disadvantage

of producing free bleeding from the clean granulations every time the dressing is changed; it is also wasteful.

(d) As soon as the surrounding parts of the ulcer are clean treatment with an antiseptic can be begun, reverting to one or two more penicillin dressings if spread occurs from the sloughing areas. This alternating treatment can be carried on until the whole ulcer is clean during which time epithelialization will have been taking place from the edges.

This technique was used, with aseptic precautions, in the above series of cases. The average number of penicillin dressings used was 5.5.

MEDICAL TREATMENT OF INTESTINAL OBSTRUCTION

By S. M. SADIQ

Assistant Surgeon, Panipat

THE operative mortality of intestinal obstruction even in expert hands is 40 per cent and may be 80 per cent (British Encyclopædia). If that is the case in the best equipped hospitals under the safest conditions what should be the mortality in the districts which lack x-rays, diathermy, expert anaesthetist and modern instruments, and when the patients come in late at the stage of hiccough and sometimes faecal vomiting.

This is why I took to simple injections of pituitrin, sometimes combined with eserine and atropine for the treatment of obstruction, irrespective of its cause. I must admit that the treatment is definitely blind, but the results so far attained in my opinion justify this treatment. It may be that faecal impaction, tubercular hyperplasia, volvulus and intussusception constitute the commonest causes of intestinal obstruction, as it does not stand to reason that mechanical obstruction due to bands or tumours could be relieved by this treatment. Due to lack of x-rays I have not been able to assign the exact cause in each case nor been able to judge the level of obstruction, that is, whether the small or large intestine is its site, but taking all types of obstruction at ages varying from 14 years upward (I have not as yet tried the treatment on infants and children as none have so far been brought in) the treatment with pituitrin gives a mortality rate of 10 per cent. I have given this treatment to 10 patients by now, out of which one was discharged uncured. This is rather a small number but the disease is not common. The method adopted by me is first to give two consecutive enemata at an interval of one hour and if the result is negative to start injections of pituitrin 1 c.c. subcutaneously till four injections are given. Hot turpentine stupes are given as a routine. Nothing is allowed by mouth. Intravenous glucose and saline are necessary in moribund cases. Early cases come off successfully within three injections, but one may have to continue with courage

for even 48 hours, combining atropine and eserine at occasions as I did in one of my cases.

After the first or the second injection a castor oil enema with 4 ounces of castor oil is given in the knee-elbow position. One sign that I have noted specially is the diminution, however slight, of distension after the first or the second injection and this is a very hopeful sign. If there is no result the enema is repeated after every third or fourth injection till the patient passes a stool. Once there is a good result, castor oil is given by mouth to clear the bowels and no further treatment is required except a very gradual return to normal diet.

man, obstruction for 36 hours. No vomiting, pulse good, cured after three injections.

He came again after one year in exactly similar circumstances and was cured again. He developed diarrhoea two months later. There was a mass in the right iliac fossa obviously looking like a tubercular caecum. He had several times been advised to get himself x-rayed and go in for some surgical treatment but he never agreed to open operation. In this case the cause of obstruction both times had been plastic tuberculosis.

Other cases (all recorded in Panipat Civil Hospital) for sake of brevity are as follows :—

Number	Name	Age	Duration	Admitted	Discharged	Cured/ otherwise
5	Baru	14	3 days	22-11-44	24-11-44	Cured
6	Makhan	60	5 "	9-1-45	11-1-45	Otherwise
7	Mohammad	32	2 "	27-4-45	2-5-45	Cured
8	Rashid	30	14 hours	18-12-45	19-12-45	"
9	Sharifan	30	5 days	21-1-46	31-1-46	"
10	Chorya	30	4 "	21-2-46	26-2-46	"

Case 1.—The first case was a woman, aged 30, pregnant 7½ months, did not agree to operative interference or going to Amritsar or Lahore Hospital. She wanted some sort of medical treatment only. This case is on Hoshiarpur Civil Hospital record between August to November 1937. It was fully explained to her that the injection treatment might cause her the loss of her child, but she agreed. There was no vomiting, abdomen was markedly distended, pulse was good. No visible peristalsis was present. After the usual method of diagnosis, 1 c.c. pituitrin was given subcutaneously and repeated after one hour. She passed a stool after the second injection. Castor oil two ounces was then given by mouth and she passed several motions. Fortunately there was no miscarriage.

Case 2.—Lakhi, aged 38 (record of Sonepat Hospital, 1942), obstruction was of 96 hours' duration, marked facies hypocritica, marked abdominal distension, peristalsis visible at upper part of abdomen. Vomiting had started 24 hours ago, but was only bilious. Pulse was still fair. Two enemata repeated at an interval of one hour produced no result. The injection treatment was started and continued for 24 hours with no relief. Atropine, alone and in combination with pituitrin, was then given every two or three hours for another 24 hours, but without any benefit. The condition of the patient was stationary, he was getting colic every now and then, but passed nothing. After almost 48 hours, with turpentine stupes, flatus tube, repeated enemata and not less than 25 injections, he passed a stool and later on made an uneventful recovery. He is up till now hale and hearty.

Case 3.—Rama, aged 25 (also Sonepat Hospital record, 1942). An emaciated young-

Rectal examination was negative in all cases. Out of 10 cases only one was unsuccessful, giving a mortality of 10 per cent.

Summary

Pituitrin administration is definitely of value in cases of intestinal obstruction. At least this should always be tried before finally deciding on any operative interference.

I am thankful to Captain Mohammad Ajmal Hussain, R.C.M.S., Civil Surgeon, Karnal, for allowing me to publish these cases.

OBSERVATIONS ON AGRANULOCYTOSIS COMPLICATING INDIAN KALA-AZAR

By P. C. SEN GUPTA, M.B. (Cal.)
Officer-in-charge, Kala-azar Research Department
and

N. K. CHAKRAVARTY, M.B. (Cal.)
Assistant Research Worker, Kala-azar Inquiry, I.R.F.A.
(From the Calcutta School of Tropical Medicine)

AGRANULOCYTOSIS occurring in a case of kala-azar is a grave complication. It has been reported to occur in about 7.6 per cent of cases of Chinese kala-azar by Huang (1940). The occurrence of this complication has been regarded as very infrequent in Indian kala-azar (Napier, 1943), the first proved case being reported in 1943 (Das Gupta and Sen Gupta, 1943). During the period of last one year, however, 3 cases of kala-azar admitted under the senior writer were found to develop agranulocytosis. One of these cases has already been reported by us (Sen Gupta and Chakravarty, 1945). In this paper it is proposed to present the notes of all these 3 cases in full detail and discuss the clinical features and the treatment of this serious complication of kala-azar.

Case I.—The patient, an Indian boy, aged 10 years, was admitted on the 28th May, 1945, for irregular fever without chill and rigor for 3 months, emaciation and weakness, and bleeding from the gums for one month. On admission the patient was found to be very weak and anæmic and emaciated. Temperature—102°F., pulse/respiration—138/36. Heart—no abnormality except tachycardia. Lungs—signs of bronchitis. Liver—just palpable. Spleen—enlarged 3½ inches below the 9th rib. *Laboratory investigations:* Urine—no abnormality; stools—hookworm and ascaris ova; blood group B; aldehyde, antimony and complement fixation tests—positive.

Blood counts—

Date	Hb, gm. per cent	RBC in million	MCV	MCH	MCHC	WBC in 1,000	Neutrophil	Lymphocyte	Monocyte	Eosinophil	Plasma cell
20-5	5.91	2.34	91.8	25.2	27.7	1.6	2	59	38	0	1
30-5	1.1	1	54	44	0	1
1-6	1.0	0	60	40	0	0
2-6	1.1	0	58	39	0	3

Agranulocytosis was thus seen before any treatment was given.

On 29th May, 1945, it was found that the patient had high fever of 104°F., and was looking very ill. Some purulent blisters surrounded by a zone of erythema had developed over the chin and over the abdomen. The tongue was not sore and the patient had no difficulty in swallowing. Pulse/respiration—144/40 per minute. Blood count showed agranulocytosis. The patient was put on penicillin 20,000 units intramuscularly every 3 hours, sodium antimony gluconate intramuscularly and liver extract parenterally, besides various supportive treatments. Pentnucleotide was not available. During the next 2 days the purulent blisters, which had yielded pure growth of *Staphylococcus aureus*, subsided but the general condition did not show any improvement. Signs of peripheral circulatory failure developed on the 31st May, and the condition did not respond to serum transfusion, suprarenal cortical extract, and various other therapeutic measures. The patient died on the 4th June, 1945.

Case II.—The patient, an Indian male, aged 30 years, was admitted on the 21st February, 1946, for: (1) *Irregular attacks of fever resembling malaria for 3 years.* The fever used to respond to quinine in the beginning but relapses occurred. About 5 months back following an attack of high fever, the patient developed a foul-smelling sore (canerum oris) over his palate. He was treated for this condition by the local doctor and the ulceration healed slowly after one tooth with a bit of bone had separated out. But the fever along with progressive weakness persisted. (2) *Cough with expectoration.* This

commenced with the ulceration in the mouth and gradually became worse, and 2 months back, he noticed a swelling over the precordial area. This swelling subsided to a great extent more or less spontaneously but a few days preceding his admission into the hospital the swelling reappeared. (3) *A scaly eruption all over the body.* This usually came on every winter and disappeared in spring or summer. The present attack was said to be more extensive.

On admission, the patient was found to be very weak, emaciated and anæmic. There was a generalized dermatitis somewhat resembling pellagrous dermatitis all over the body. One upper premolar tooth of the left side was missing. The liver was enlarged as also the spleen which

was enlarged up to 4 inches. *Heart:* apex beat could not be located with certainty, the sounds were normal. *Lungs:* showed signs suggestive of fluid in the left pleural cavity. There was a swelling over the precordial region in the lower and outer part, the swelling was diffuse and tender over the ribs.

Laboratory investigations showed positive indications of kala-azar along with marked anaemia.

Skiagram (23rd February, 1946).—Fluid with a horizontal level on the left side—very little cardiac displacement.

Course and treatment.—As the patient was apparently suffering from pyopneumothorax he was put on a course of sulphonamides for a week. The fever subsided and the swelling also became distinctly less. Soon after this course of sulphonamides on 6th March, 1946, the patient was put on a course of pentamidine as specific treatment for kala-azar. On the 10th March, it was found that the precordial swelling was more prominent, and the patient was having high temperature, he was put on a course of sulphadiazine on the suspicion of a renewed activity of the intrapleural condition. On the 13th March, the patient complained of soreness of the tongue and slight difficulty in taking his meals. The tongue was found to be superficially ulcerated and denuded of epithelium and bleeding in places. Also there were some whitish patches over the tongue. A blood count was immediately done and it was found that the patient had developed agranulocytosis; the leucocyte count was 800 per c.mm. and there were only 2 per cent neutrophil polymorphonuclears. Sternal puncture was also done (*see table*). Sulphadiazine was immediately stopped, and in order to bring the leishmanial infection rapidly under control, sodium antimony gluconate was substituted for pentamidine. To combat agranulocytosis, pentnucleotide 10 c.c. was given intramuscularly twice a day, and whole liver extract 4 c.c. intramuscularly daily, and to combat the infections in the mouth and elsewhere, penicillin was administered intramuscularly for the next 5 days. Blood counts were made on consecutive days. On the 18th it was found that the patient was looking much brighter and afebrile. The blood count on this day showed that he had got over agranulocytosis, WBC being 1,700 per c.mm. with 54 per cent neutrophils. After this date the progress of the patient was satisfactory. The sores on the tongue gradually healed up and the size of the spleen commenced diminishing. The dermatitis was still present and had responded but slightly to niacin and liver extract injections. The

patient was discharged as clinically cured of kala-azar on 23rd April, 1946.

Case III.—An Indian female, aged 18 years, attended the kala-azar outpatients' department on the 12th April, 1946, for fever, at first intermittent, later remittent in type, of duration of about 2 years, and progressive weakness and emaciation and enlargement of the spleen. On examination the patient was found to be thin and anæmic, with accentuation of pigmentation over the forehead and face. The spleen was enormously enlarged measuring 9 inches below the costal margin and the liver was enlarged up to 2 inches below the costal margin. The heart and lungs did not show any abnormality. The aldehyde, antimony and the complement fixation tests for kala-azar were all positive and the patient was diagnosed as a case of kala-azar and she was put on aminostiburea. (The patient said that before coming to the outpatients' department she had four injections of urea stibamine.)

At the time of commencement of the injections of aminostiburea the patient was having high fever, the temperature rising up to 104°F. After she had received about 4 to 5 injections the fever subsided considerably, temperature rising up to 99°F. After she had received the 8th injection the patient started high fever and was then taken into the hospital on the 21st May, 1946.

On admission into the hospital the patient was found to be very ill and the temperature was rising up to 104°F. The injections of aminostiburea were continued for 2 consecutive days but without any effect on the fever. There were no signs of any systemic complication to explain the persistence of the high fever and the general deterioration of the patient. It was then suspected that probably the patient had developed agranulocytosis, the reason for this being the similar apparently unexplained pyrexia seen in the previous cases, the presence of a very thin whitish filmy patch over the left tonsil and the swelling of the submaxillary lymph glands of the left side. (On culture *St. viridans* and *Staphylo aureus hæmolyticus* were isolated from left tonsil.) There was however no soreness of the tongue or any difficulty in

swallowing. A blood count was done and it was found that there were no granulocytes. The total WBC count was only 1,500 per c.mm.

The patient was immediately put on pentnucleotide 10 c.c. intramuscularly twice daily, liver extract (crude) 4 c.c. intramuscularly daily, penicillin 20,000 units intramuscularly every 3 hours besides other symptomatic treatment.

In addition she was given injections of percorten and coramine by mouth from the 4th day of commencement of treatment for agranulocytosis on account of the very low blood pressure (85/35) and gallop rhythm of heart sounds and asthenia. The specific treatment for kala-azar was withheld for the first 2 days on the suspicion that the antimonial might be responsible for producing agranulocytosis. But as it was found that there was no improvement during these days of treatment, the specific treatment was re-started, the drug used being sodium antimony^v gluconate. On the next day the temperature started coming down and reached normal. During these days, though the swelling of the lymph glands and the patch over the tonsil had disappeared within 2 days of commencement of treatment, the fever and the general condition had remained unaffected and patient had remained desperately ill; the temperature had remained near about 104°F., and energetic hydrotherapy had to be adopted. The blood count on the 5th day showed that the neutrophils were 19 per cent of 1,550 leucocytes (i.e. 294.5 neutrophils per c.mm.). Except for an attack of diarrhoea the subsequent progress of the patient was uneventful. She required a full course of specific treatment for kala-azar with sodium antimony^v gluconate for clinical recovery from kala-azar. Blood counts are seen in the table.

Penicillin was continued for 5 days, liver extract and pentnucleotide for a week.

Fever.—There was a high fever, the temperature ranging between 102° and 105° in all the cases concurrently with the development of agranulocytosis and this persisted till this complication was relieved. The patient who developed agranulocytosis about the middle of a course of injections of a pentavalent antimonial was almost afebrile for days preceding the onset of this complication, which was accompanied by high rise of temperature. This was also noted in case II. The other patient, an untreated case of kala-azar, was admitted with agranulocytosis and he had high fever.

The fever was found to persist at a high level as long as the condition of agranulocytosis persisted, even when there was no apparent infection anywhere, and all the infections present had been relieved by the administration of penicillin. Only when the total neutrophil count in the peripheral blood rose to above 250 or so per c.mm. did the temperature come down (see temperature charts).

Other general symptoms.—Deterioration of the general condition and prostration were noted in all cases. This was a striking feature because in the uncomplicated cases of kala-azar the patients do not feel the fever to any great extent, prostration is exceedingly uncommon and they can usually go about with a temperature of 103°F. or so.

It appears that there is some danger of circulatory failure in agranulocytosis complicating kala-azar. One patient (case I) developed peripheral circulatory failure and another (case III) showed very marked lowering of blood pressure along with gallop rhythm of the heart sounds.

Soreness of the mouth and anginal symptoms.—Affection of the mucous membrane of the mouth and pharynx was found to be entirely absent in case I, and in the other 2 cases, there was

Discussion

Clinical features.—The principal symptoms present in the cases reported here are considered under the following headings: fever, soreness of the mouth and anginal symptoms, secondary infections, other general symptoms, and the hæmatological changes.

only a slight degree of inflammation with the formation of very inconspicuous membrane over the tonsil along with a swelling of the submaxillary lymph glands. There was no dysphagia in any case. This latter symptom was well marked in the first case reported in 1943 (Das Gupta and Sen Gupta, *loc. cit.*)..

Other secondary infections.—It is said that secondary infections are responsible for the fatal termination in agranulocytosis. In case I that

CASE I.

CASE II.

CASE III.

went to a fatal termination there were seen several purulent blisters over the face and the trunk but these subsided entirely within 2 days of penicillin therapy.

No other secondary infection was seen in this case yet the patient died. The other 2 cases did not show any secondary infections. Blood culture done in one case did not yield any growth of bacteria.

Haematological changes.—In these 3 cases the leucocyte count at the onset of agranulocytosis varied from 800 to 1,600 per c.mm. with the neutrophils varying from 0 to 2 per cent, the absolute number of the neutrophils varying between nil to 32 per c.mm. Sternal puncture done in one case showed definite paucity of the cells of the granulocyte series.

It was found that the number of granulocytes rose to the level of 250 or so after about 4 to 5 days' treatment for agranulocytosis.

Treatment

In a recent review of the treatment of agranulocytosis (Annotations, *Lancet*, 1946), it was pointed out that though Dameshek was of the opinion that the death in agranulocytosis was not due to this condition as such but to bacteraemia and septicaemia which invariably ensued, the evidence of such sepsis was not very clear. Also the use of penicillin has been regarded as very valuable for no convincing reason, because the patients who were treated with penicillin had other therapy in addition, viz. pentose nucleotide, liver extract, blood transfusion, etc. The view expressed by the writer about penicillin is that it is only useful as an antibacterial drug without any depressant action on the granulocytes.

The treatment adopted in the above 3 cases consisted of (a) penicillin to combat or prevent sepsis, (b) leucopoietic drugs, pentose nucleotide and whole liver extract (pentnucleotide was not available for case I), (c) specific treatment for kala-azar, (d) general supportive measures, including intake of adequate nourishment, vitamins and glucose, and (e) symptomatic treatment for high fever, circulatory failure, etc.

Penicillin was found to control and eradicate the infections in the mouth in these cases within 2 or 3 days and no serious secondary infection developed during the course of its administration. But it had apparently no effect on the fever in any case.

The *leucopoietic* drugs, pentnucleotide and liver extract are well recognized for their value in agranulocytosis. Pentnucleotide was given in 10 c.mm. doses at least twice daily by intramuscular injections and whole liver extract was given in 4 c.cm. doses intramuscularly daily.

Specific treatment of kala-azar with pentavalent antimonials.—It is well recognized that agranulocytosis may occur in untreated kala-azar as well during treatment. The marked granulopenia and anaemia in kala-azar are regarded as caused by the replacement of the

hæmo- and leucopoietic cells in the marrow by the marked proliferation of the macrophage cells, a high proportion of which are parasitized. It is possible that in some cases of kala-azar agranulocytosis is due to severity of infection, the excessive proliferation of the macrophages almost entirely replacing the formative elements in the marrow. Sternal puncture smears of 2 cases (case II and the case reported in 1943) showed a very marked aplasia of the cells of the granulocytic series. Also in both these cases unusually large numbers of parasitized and non-parasitized macrophages were seen. Zia and Forkner (1934) also published photomicrographs of sections of bone marrow showing large number of parasitized macrophages and extreme paucity of the myelocytes and more mature granulocytes.

In the cases where agranulocytosis developed during the course of treatment with pentavalent antimonials the workers in China were of the opinion that antimonials played some part in precipitating an attack of agranulocytosis. This is no doubt possible, though repeated injections of antimony compounds have never been found to possess any significant action on the blood picture of experimental animals by Forkner. The other possibility in such cases is that treatment may either be inadequate in controlling a severe infection or cause a further stimulation and proliferation of the macrophage cells thus leading to a further depression of granulopoiesis. It is not possible just at present to decide either way. But it may be mentioned that the patient, who developed agranulocytosis after receiving about a dozen injections of antimonials, required a second full course of injections of a different antimonial for her clinical cure of kala-azar.

The question whether the pentavalent antimonials should be used or not during agranulocytosis is however not difficult to decide. In untreated cases of kala-azar it is justifiable to administer antimonials, and in the cases where the condition develops during the course of treatment with an antimonial, it is more reasonable to withhold antimonials till the condition subsides, and then start treatment of kala-azar with a different antimony compound.

There is little to discuss about the general supportive measures and symptomatic treatment. Blood transfusion is regarded by some workers as valuable; but unless the patient is severely anæmic, there does not seem to be any indication for this procedure which may prove risky in patients with high temperature of 103° or higher. Chances of hyperpyrexial reactions are not inconsiderable even with blood samples from well-regulated blood banks and when the technique of transfusion is beyond reproach.

Summary and conclusions

Three cases of agranulocytosis complicating kala-azar are reported and the clinical features discussed. It has been found that the usual

lesions affecting the mucous membrane of the mouth and the pharynx may be very inconspicuous or even absent in some cases. The high fever that is associated with agranulocytosis persists even when there is no apparent infection anywhere and the slight infections present entirely relieved by penicillin, till about 250 or more neutrophil cells appear in the peripheral blood.

The treatment of this condition is discussed. Penicillin relieves the oral lesions if present and it can prevent secondary infection with a large group of organisms. The well-known leucopoietic agents, pentnucleotide and whole liver extract should be administered in full doses. The specific treatment for kala-azar with pentavalent antimonials should be given in previously untreated cases. But in the cases where agranulocytosis develops during antimony treatment it is preferable to withhold the specific treatment of kala-azar till this complication has been relieved. The treatment should include general supportive measures, viz, adequate nourishment and fluid intake, and symptomatic treatment for toxæmia, circulatory failure, etc.

[P.S.—After this paper had been sent for publication one more case of previously untreated kala-azar complicated by agranulocytosis was admitted under my care. The diagnosis was made on clinical grounds and confirmed hæmatologically and by finding leishmania on sternal puncture. The treatment was by a pentavalent antimonial-penicillin-pentnucleotide liver extract—therapy along with general supportive measures. The patient made an uneventful recovery, the high fever persisting till the subsidence of agranulocytosis.—P. C. S. G.]

THE ÆTIOLOGY OF 'PHRYNODERMA'

By C. GOPALAN, M.D.

(From the Nutrition Clinic and Research Ward, Stanley Hospital, Madras, and Nutrition Research Laboratories, Coonoor)

A LARGE number of cases of phrynoderma was observed among the patients that attended the Nutrition Clinic. In the present investigation, the following observations were made regarding (a) the incidence of phrynoderma and (b) the response of the disease to certain lines of treatment.

Incidence

Age and sex.—In the course of the investigation, 116 cases of phrynoderma were observed. Most of these cases belonged to the poor class and a few to the so-called 'lower middle' class.

The distribution of the cases according to sex and age groups is given below :—

	Below 5	5 to 10	10 to 15	15 to 20	Above 20
Males ..	1	12	20	11	7
Females	2	18	28	13	4

It is noteworthy that nearly 70 per cent of the cases were between 5 and 15 years. The incidence in adults was relatively low. A significant feature was the strikingly low incidence, less than 3 per cent, in children below 5 years.

The age and sex incidence of a group of 134 cases of xerophthalmia observed in the course of the investigation was as follows :—

	Below 5	5 to 10	10 to 15	15 to 20	Above 20
Males ..	36	21	9	5	2
Females	28	18	7	5	3

Nearly 50 per cent of cases of xerophthalmia were children below 5 years. Thus, accepted manifestations of vitamin A deficiency were predominantly present in children below 5

of nutritional deficiency. The others presented obvious signs of malnutrition as shown below :—

	B ₂ complex deficiency signs	(1) + xerophthalmia	Xerophthalmia alone
Number of cases of phrynoderma.	91	14	4

Thus in nearly 92 per cent of cases of phrynoderma, clinical evidences of B₂ complex deficiency were present. On the other hand accepted clinical evidence of vitamin A deficiency was present in about 15 per cent of cases of phrynoderma.

The incidence of phrynoderma in a group of 134 cases of xerophthalmia drawn from the Ophthalmic and Nutrition departments was also investigated and is represented below :—

	With phrynoderma unassociated with B ₂ complex signs	With phrynoderma associated with B ₂ complex signs	Without phrynoderma
Number of cases of xerophthalmia.	4	14	116

Seasonal incidence.—The incidence was high in the colder months of the year. With the coming in of the hot season, there was a distinct decline in the number of cases observed. It may be pointed out that the average attendance at the Nutrition Clinic was nearly the same throughout the period of the investigation.

	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	March	April	May	June	July
Number of cases	6	11	19	22	21	16	8	3	2	3	2

years; and it was in this very age group that phrynoderma was particularly rare.

Associated deficiency signs.—Of the 116 cases observed, 4 cases did not show any clinical sign

Treatment

Therapeutic trials were carried out on 37 cases of phrynoderma with six kinds of treatment as indicated in table I.

TABLE I

NUMBER OF CASES OF PHRYNODERMA

Treatment	Total	Associated with B complex signs alone	Associated with B complex signs and xerophthalmia	Associated with xerophthalmia alone
1. Vitamin A concentrate ..	5	1	3	1
2. Nicacinamide ..	4	3	1	..
3. Riboflavin ..	5	3	2	..
4. Yeast extract ..	9	6	2	1
5. Linseed oil ..	6	5	1	..
6. Yeast extract + linseed oil ..	8	6	2	..

These cases were treated as out-patients so that the hospital diet may not vitiate the results. The patients continued to subsist on their usual diets during the period of treatment and did not get any drug other than that used in the investigation. Treatment on the different lines was carried out for periods ranging from 5 to 6 weeks. To assess the result of the treatment, it was found convenient to 'grade' the cases after treatment as follows (see figures, plates I and II).

Grade I—Cases in which there was definitely no improvement.

Grade II—Cases in which the improvement was 'not definite' or 'doubtful'—inconclusive. In this grade are included cases in which the 'eruptions' appeared to have become relatively sparse in places but had not disappeared partly or entirely from any area.

Grade III—Cases in which improvement was definite but not complete. In this grade are included cases in which at the end of treatment the 'eruptions' had disappeared partly or entirely from certain areas and over other areas they had become sparse.

Grade IV—Cases in which improvement was 'complete'. The 'eruptions' had disappeared almost completely leaving behind small circumscribed areas of pigmentation.

The treatment adopted and the response thereto are indicated in table II.

these therapeutic tests, are all fair sources of fatty acids.

Another point that has to be considered in a number of these therapeutic tests is with regard to their prolonged duration. It has been shown that the incidence of the disease is definitely influenced by seasonal factors and the same observation has been made by several workers. It is a question, however, whether seasonal variation can influence the course of an established case; but the possibility may not be denied. The possible contribution of the seasonal variation to the result of treatment has to be remembered in assessing the value of therapeutic tests spread out over several months.

Several workers including Frazier and Hu (1936), and Frazier, Hu and Chu (1943) have remarked on the lack of correlation between the incidence of phrynoderma and accepted signs of vitamin A deficiency. Frazier and Hu (1931) suggest that the preponderant incidence of phrynoderma in the second decade is related to the development of the pilosebaceous glands occurring round about the pubescent period. If this were so, it would explain the absence of phrynoderma in cases of keratomalacia occurring in infancy and early childhood, but cannot explain either the frequent absence of phrynoderma in older cases of keratomalacia or the frequent absence of keratomalacia in cases of phrynoderma. Hawes (1945) on the other hand

TABLE II

Treatment	Daily dosage	Number of cases	RESPONSE			
			Grade I	Grade II	Grade III	Grade IV

Yeast extract + linseed oil ..	4 to 6 drachms + 1 ounce of oil.	8	1	7

* Parenterally in 3 cases and as capsules orally in 2 cases.

Discussion

The vitamin A deficiency hypothesis.—Much of the support for the vitamin A deficiency hypothesis has been derived from the observation of several workers that administration of substances rich in vitamin A—fish liver oils—over prolonged periods has cured the skin disorder. Stannus (1945) has pointed out that the tests employed have generally been not exclusive and control observations have been wanting. 'For many cod liver oil has been synonymous with vitamin A and supplements to the diet have often been made at the same time'. It must be remembered that the fish liver oils used by some workers, and cotton seed oil, groundnut oil, etc., employed by some others as vehicles for the vitamin A concentrate in

suggests that the predominant incidence of phrynoderma in this period may be due to a marked disparity between the carbohydrate intake and fat intake in the diet of the poor in this period which may accentuate a relative deficiency of some fatty acid.

Frazier and Hu (1936), and Lehman and Rapaport (1940), remarking on the absence of xerophthalmia in several cases of phrynoderma, suggest that in the evolution of the clinical signs of vitamin A deficiency, the skin manifestations may precede the ocular signs. Even if this were true, it would not explain the frequent absence of phrynoderma in advanced cases of xerophthalmia. Moreover, Jeghers (1937) and Getz (1944), who attempted to induce vitamin A deficiency in man, found that the very first

manifestations were always ocular. Bloch (1917) and Pillat (1929) who studied the condition of the skin in cases of keratomalacia did not find follicular lesions. Bloch (1917) reported on the other hand 'a dry shrivelled and scaly condition of the skin' and Pillat (1929) described the skin in keratomalacia as 'slaty-grey, wrinkled, dry and scurfy'.

Lehman and Rapaport (1940) point out, in support of the vitamin A deficiency theory, that in 9 cases of phrynoderma in which there was no evidence of xerophthalmia, dark adaptation tests revealed impairment of adaptation. Sub-clinical defects cannot have the same significance as manifest clinical signs with regard to the ætiology of an associated disorder. Moreover, recent work (Kimble and Gordon, 1939; Morton, 1944; Pollak, 1945) seems to suggest that deficiency of some members of the B complex may also have some relation to the impairment of dark adaptation in some cases.

Rao (1937) concluded from a histopathological study of his cases that in the development of the disorder vitamin A deficiency may probably be an important factor. But Wolbach and Bessey (1942), reviewing the tissue changes, suggest that the disorder 'might be related to riboflavin deficiency rather than A deficiency, as previously concluded from rather inadequate evidence'. Moulton (1943) observed lesions closely resembling those of phrynoderma in rats fed on diets deficient in vitamin A. Stannus reveals that the vitamin, in this experiment, was administered in the form of a fish liver oil concentrate of high potency diluted with edible groundnut oil. The introduction of groundnut oil in the experiment would seem to vitiate its value.

The results obtained here do not support the vitamin A deficiency hypothesis. While the dosage of vitamin A used here was larger than that employed by other workers, the duration of treatment was less. However, cases of phrynoderma of comparable severity treated for the same duration on other lines improved definitely. Stannus (1945) and Hawes (1945) also failed to obtain improvement in their cases with vitamin A. Hawes employed vitamin A by injection in large doses 'without observing the slightest effect on the skin' on his cases in the East.

Yeast extract.—The observation that there is correlation between the incidence of phrynoderma and signs of B₂ complex deficiency has also been made by other workers (Platt and Gin, 1935). Nicholls (1933, 1934) reported the presence of neuritis, angular stomatitis and glossitis in several of his cases of phrynoderma.

The frequent presence of signs of B₂ complex deficiency in several cases of phrynoderma and the response of the disease to intensive treatment with yeast extract would suggest that the condition is related to deficiency of some factor in the B₂ complex. This factor is evidently something other than (or more than) nicotinic acid or

riboflavin since neither of these by itself yielded the results obtained with yeast extract.

Linseed oil.—The satisfactory result obtained in some cases of phrynoderma with raw linseed oil probably supplies the explanation for some puzzling features regarding phrynoderma. Raw linseed oil is a rich source of unsaturated fatty acids including linoleic and linolenic acids but does not contain appreciable amount of vitamin A. The failure of vitamin A concentrate to appreciably influence the skin condition in cases of phrynoderma and the success obtained, in some cases with raw linseed oil would suggest that the curative effect claimed for the fish liver oils is probably due to the fatty acids contained therein.

Yeast extract and linseed oil.—The combined use of yeast extract and linseed oil was more effective than either of these employed separately. It has been demonstrated by several workers (Burr and Burr, 1929; Hogan and Richardson, 1935; Birch, 1938) that there is a definite relationship between the metabolism of certain members of the B₂ complex and that of some unsaturated fatty acids in experimental animals. Birch and György conclude that 'in the absence of a decent supply of certain vitamins of the B₂ group, the animal is unable to make proper use of the fatty acids, or alternatively, in the absence of adequate amounts of unsaturated fatty acids, the animal is unable to utilize these vitamins'.

The lesions reported in these experimental animals, however, do not strictly parallel the lesions in phrynoderma. But it is perhaps possible in the human subjects also, that in the absence of adequate amounts of certain members of the B₂ complex from the diet, there is an imperfect utilization of fatty acids or *vice versa*; that a vicious circle is thus set up, which ultimately leads to the development of the characteristic skin lesions of phrynoderma. If this were so, one may expect to correct the disorder by supplying either the fatty acids or the members of the B₂ complex, but the results are likely to be better if both these substances are used in combination. The observations made in this investigation seem to bear out this expectation.

Summary and conclusions

1. One hundred and sixteen cases of phrynoderma were studied and the response of 37 cases to six different lines of treatment was investigated.
2. The results of the investigations have been discussed and the vitamin A deficiency hypothesis has been examined.
3. The suggestion has been advanced that phrynoderma may be due to related deficiencies of certain members of the B₂ complex and fatty acids.

I am grateful to the Superintendent and staff of Stanley Hospital, Madras, for the facilities extended to me for the conduct of this investigation.

EXPLANATION OF ILLUSTRATIONS

- 1-a and b .. A case of phrynoderma before treatment.
 2-a and b .. The same case after 6 weeks of treatment with pure raw linseed oil. The 'eruptions' have mostly disappeared but small circumscribed areas of pigmentation marking their sites still remain.
 3, 4 and 5 .. Deficiency signs associated with phrynoderma.
 3-a .. Angular stomatitis in a case of phrynoderma. The conjunctivæ appear bright and clear.
 3-b .. Skin condition of the case shown in 3-a.
 4-a .. Shows angular stomatitis with acne-form comedones on the face. Conjunctivæ appear bright and clear.
 4-b .. Skin condition of the case shown in 4-a.
 5-a .. Angular stomatitis and glossitis in a case of phrynoderma. The picture shows the patient much darker than she actually was, the conjunctiva therefore appears brownish but actually there was no evidence of xerophthalmia.
 5-b and c .. Skin condition of 5-a above.

ANEURYSM OF THE PULMONARY ARTERY WITH PATENT DUCTUS ARTERIOSUS

By R. SUBRAMANIAM, B.Sc., M.D. (Madras),
M.R.C.P. (Lond.)

Assistant Physician, Government General Hospital,
Madras

ANEURYSM of the pulmonary artery is a rare condition. In the Indian literature, the case reported by Rogers (1908) of a dilatation of the artery with atheroma seems to be the only case. Scott (1934) was able to collect 89 cases from literature between the periods of 1836 and 1934. Wahl and Gard (1931) reported a case of aneurysm of the pulmonary artery in a girl aged 19. In this case symptoms dated from birth. Pre-operative diagnosis was mitral stenosis and mediastinal tumour, no pulsation on screen. Hæmoptysis was present, blood Wassermann was negative. E.C.G. showed right side preponderance. X-ray therapy had no effect on tumour masses. The case was observed for 27 months. Definite signs of heart failure at rest developed with clubbing of the fingers. Bulging of the manubrial area increased and the patient complained of a dull pain in the same area and hæmoptysis with constant cough. The case was operated upon, and the tumour exposed and incised. Blood gushed out and the patient died. Autopsy showed wide open patent foramen ovale. Pulmonary artery and the two branches up to the point of entry into the lung were greatly dilated. Wilkinson (1940) reported a case of aneurysmal dilatation in a girl of 10, with rupture of the pulmonary aneurysm into the pericardium. Holmes (1944) has reported a case of patent ductus arteriosus associated with pulmonary aneurysms and infective endocarditis.

Ætiology.—While, undoubtedly, the commonest cause of aortic aneurysm is syphilis, it is not so in the case of pulmonary artery aneurysm. Diseases of the pulmonary artery and its branches are of manifold ætiology and the different age groups are affected almost equally.

1. Aneurysm of the pulmonary artery seems to be most often congenital in origin. Congenital dilatation of the pulmonary artery is associated with other congenital defects, as patent ductus arteriosus, and patent inter-arterial (the commonest) or inter-ventricular septum. The pulmonary valves are in most cases bicuspid. Trauma, as by a bullet wound of the chest, has caused aneurysm. Rupture of the dilated aneurysm has been observed in a few cases. It is noteworthy that in nearly all cases of patent ductus arteriosus, the pulmonary artery is dilated to some extent. Aneurysm of the patent ductus arteriosus has also been recorded.

2. Less often it is associated with syphilis. Warthin has demonstrated the spirochæte in the aneurysmal wall in one case.

The other conditions in which the pulmonary artery is dilated are :—

3. Rupture of an aortic aneurysm into the pulmonary artery.

4. Fistula formation between the aorta and the pulmonary artery due to ulceration (syphilitic often, atheromatous rarely), mechanically same as patent ductus arteriosus.

5. Mitral stenosis.

6. Congestive heart failure cases, irrespective of the primary cause of the heart failure.

7. In pulmonary tuberculosis, the branches of the pulmonary artery stretching across a tuberculous cavity may undergo aneurysmal dilatation.

Clinical features.—These cases are very difficult to recognize clinically. They may simulate either an aortic aneurysm or a mediastinal tumour. Ante-mortem diagnosis has been made in a few cases. The aneurysm of the pulmonary artery occurs at a younger age than the aortic aneurysm. Cyanosis and dyspnoea occur. Pulsation is present in the left side of the chest, close to the sternum, particularly in the second and third interspaces. Persistent and troublesome cough may occur. These patients die of rupture of the dilated artery, or of septic endocarditis, and rarely of congestive heart failure or of inter-current infection. Radiologically, these aneurysms may or may not show pulsation. In a number of cases, including the one reported here, absence of pulsation has been noted. Henschen believes that the diagnosis of pulmonary artery aneurysm can be made by the following features :—

1. Prominence of the 2nd and 3rd costal cartilages with well-defined dullness and an x-ray shadow in this area.

2. Intense cyanosis and other signs of congestion, hæmoptysis and substernal pain.

3. Pulsation and well-defined thrill and murmur in the second and third left interspaces.

4. Loud superficial rasping systolic murmur.

5. Right side cardiac hypertrophy.

6. Absence of usual signs of aortic aneurysm, i.e. dullness to right, difference in pulse and recurrent laryngeal paralysis.

7. Absence of dilatation or hypertrophy of the left heart, i.e. apex dullness within the mid-clavicular line.

Case report

A Hindu male, age 25, came to me nearly three years ago and was kept under observation for a month and was discharged as a case of mediastinal tumour. He complained of swelling and pain over the pericardium and pain in the joints of two years' duration. He noticed gradually increasing bulge over the pericardium, dyspnoea on exertion and pain in the precordial area. Sometimes the patient had blood-stained sputum.

General condition.—A fairly nourished person. Precordial bulge on the left side close to the

body of the sternum. No cyanosis or clubbing of the finger nails.

Cardiovascular system.—Heart boundaries on the left side $2\frac{1}{2}$ inches outside left mid-clavicular line. Upper border 3rd rib on the right side lateral sternal line. The entire pericardium and the area about 3 inches from the lateral border of the sternum over the 2nd and 3rd left interspaces were dull on percussion. Pulsation was also present over those areas. Reduplicated first sound in all areas. Diastolic murmur heard between the mitral and pulmonary areas, particularly close to the sternum.

Respiratory system.—Left inter-scapular region dull and breath sounds feeble in the same area, otherwise nil abnormal.

Alimentary system.—Nil abnormal.

Laboratory findings.—Urine normal. Blood : total R.B.C. 4 to 3.7 million per c.mm. W.B.C. 7,000 per c.mm. Haemoglobin 85 per cent. Blood Wassermann negative, blood pressure arm : 120 to 75, legs 140 to 95. X-ray of the chest showed a shadow of the size of a tennis ball seen in continuation with the heart shadow to the left (figures 1, 2 and 3, plate III). Lateral view of chest showed no erosion of ribs. Screening with barium meal showed no deviation of the œsophagus. Very little pulsation in the shadow compared to the dynamic pulsation of the heart (? transmitted pulsation from the heart). E.C.G. left ventricular preponderance. Artificial pneumothorax was done and there was a broad band of lungs adhering to the chest wall with no displacement of the tumour mass.

Treatment.—The patient was put on iodides without any relief of the symptoms. Later, he was put on sodii salicylas 2 drams a day for joint pains with considerable relief of symptoms. Deep x-ray therapy gave relief to the chest pain but no appreciable change in the tumour mass after a course of Roentgen therapeutic test dose.

This patient came again after a period of two years and was under my observation for over two months before he died. He had developed by that time cyanosis of the lips, a tendency to clubbing of the finger nails, but he had not lost any weight nor did he show any signs of wastage. He was comfortable when at rest. Even walking a few feet made him breathless. Clinical and radiological examinations were identical to the conditions that obtained nearly three years ago. The diagnosis in this case was mediastinal tumour. The diagnosis was based on pressure symptoms and the absence of pulsation on screening. The general condition of the patient was the same for nearly a period of three years. This ruled out the possibility of malignancy. The fact that the patient, when at rest, was fairly comfortable, and only exertion caused dyspnoea, was sufficient evidence of a space occupying benign tumour in the mediastinum (dermoid or a cyst). A very sharp outline of the tumour suggested the possibility of aneurysm, but was missed because his general condition after nearly three years

was not worse. The blood Wassermann being negative was also taken as a point against aneurysm. The rare possibility of the pulmonary artery aneurysm did not suggest itself clinically. Operation was decided upon under cyclopropane anaesthesia. Soon after anaesthesia was started, the patient turned intensely cyanotic and respiratory failure occurred.

At a partial autopsy the following features were noted :—

The heart was enlarged. The right auricle was dilated a little more than normal, and the musculature showed slight hypertrophy. Foramen ovale closed, tricuspid valves normal. The right ventricle was very much reduced and the wall much thickened, to nearly the thickness of a hypertrophied wall of the left ventricle (figure 6, plate IV). Thickness varied from 17.5 mm. to 23.5 mm. There was no defect in the inter-ventricular septum. The pulmonary valves were bicuspid and looked normal. Beyond the valve the left pulmonary artery was dilated to more than the size of a tennis ball. There was a communication between the pulmonary artery and aorta, widely dilated patent ductus arteriosus. Diameter of the patent ductus was 11.5 mm. The opening into the aorta was just distal to the origin of the left subclavian artery. There was a horse-shoe shaped septum from the roof of the aneurysm (figures 4 and 5, plate IV), the end of the septum arising 10 mm. above the pulmonary valves. The distance between the pillars of the septum was 45 mm. and the height from the wall to the free end of the septum measured 60 mm. Two explanations are offered for this septum. One is that it is the prolongation of the ductus free end into the aneurysm. The other is that the septum represents an aberrant pulmonary valve left behind during the development. But the histological appearance did not show any valvular element in the septum. It was the left pulmonary artery that was markedly dilated into an aneurysm. The aneurysm measured 10.45 cm. \times 8.4 \times 10 cm. and was compressing the left lung. Thickness of the wall of the aneurysm minus the thickness of the pericardium was 1.75 mm. On opening into the aneurysm sack it was found to contain only liquid blood. No laminated clot was present. The intima of the aneurysmal sack showed atheromatous patches and the patent ductus was healthy. Left auricle was normal and the wall of the ventricle showed some amount of hypertrophy. Thickness varied from 19.5 mm. to 20.5 mm. The aorta showed atheromatous changes near the origin of the left common carotid and left sub-clavian arteries. The aortic valves and cusps were normal. The aorta did not show any narrowing where the patent ductus opened into it or beyond it. The coronary arteries were normal. Right pulmonary artery was found to be moderately dilated and the diameter was 24 mm. The pericardium was thickened and adherent. Part

of the pericardium on the posterior aspect of the right auricle was markedly thickened and calcified.

Histological appearance of the wall of the pulmonary artery aneurysm did not show any evidence of rheumatic focus.

Discussion

This case very closely resembles the case reported by Wahl and Raymond. The patency of the ductus arteriosus was not evident during life. Patent ductus and pulmonary aneurysm have been recorded in the literature. The lack of pulsation, the negative Wassermann reaction, and the lack of signs and symptoms of the commoner aortic aneurysm, led one to diagnose a mediastinal tumour. Lack of wasting or cachexia led one to eliminate the possibility of malignancy. More importance ought to have been attached to the sharp outline in the x-ray picture and the subjective relief of symptoms the patient had with salicylates should have put one on guard. At the autopsy it was noted that there was no adhesion between the lung and the chest wall. It was aneurysm which had come in contact with the chest wall and given the false impression of an adherent lung after pneumothorax. It is noteworthy that the patient did not exhibit any of the symptoms associated with patent ductus. The lateral view of the chest was scrutinized after autopsy and an erosion of the rib could be made out.

The case was mistakenly diagnosed during life as a benign mediastinal tumour (? dermoid). Autopsy showed it to be a congenital anomaly. The other anomalies as patent foramen ovale and patent inter-ventricular septum were absent.

My thanks are due to Rao Bahadur Dr. T. Satakopan, Major F. A. B. Sheppard, I.M.S., and the Superintendent of the Government General Hospital, for permitting me to report this case, and to the Pathology Department staff (Madras Medical College), who helped me to study the specimen photographs of the same and the Radiology Department of the Barnard Institute of Radiology for helping me in the radiological work connected with this case.

A Mirror of Hospital Practice

FŒTAL MALPRESENTATION IN A CASE OF SIMPLE GOITRE

By (Mrs.) I. DEVADAŞAN LYALL,
M.B., B.S. (Punjab), D.T.M. (Cal.)

Medical Officer in-charge, Clara Swain Hospital,
Methodist Mission, Bareilly, U. P.

THAT this place is in a goitrous district has not been reported previously. This fact was observed recently when a local school medical inspection was done, and a number of slight enlargement of thyroid cases noted without any symptoms whatsoever. A graph is given below showing the incidence of enlarged thyroid in different age groups.

Case report

With this study in the background, the following case is reported:—

Patient R. S. no. 928, age 18 years, was admitted on 7th August, 1946. She had a simple goitre, the size of an orange. Primigravida, full-term pregnant, had been in labour for 9 hours, membranes had ruptured 4 hours before admission and she had been examined by village dais.

On examination: Pelvis normal, head in the brim, partially engaged. Per vaginam, cervix 2 fingers dilated, membranes absent, brow felt.

A trial labour was given hoping that a deflexed head would flex and so would effect a normal delivery. Twelve hours later: Per abdomen progress nil; foetal heart indefinite. Per vaginam, cervix still 2 fingers dilated, canal completely taken up, head still not flexed. Duration of labour 21 hours. Cæsarean section done as non-dilatation of os prevented any form of delivery via natural passages and mother appeared exhausted.

A dead female infant was removed with enlarged thyroid gland, the size of a walnut. The bones of both forearms were bent. For lack of facilities, a radiological examination was not done, but clinically it was suggestive of rickets.

Mother recovered after a mildly febrile puerperium.

It is not justifiable to draw any conclusion from a single case report but attention may be drawn to the following points:—

1. A pregnant woman with enlarged so-called simple goitre is probably liable to have a delay in dilatation of cervix.

2. The foetus in a pregnant goitrous mother is liable to have enlargement of its thyroid, too.

3. A swelling in the neck, even as small as a walnut, may prevent flexion of head in foetus during labour.

4. Such a foetus tends to have some alteration in its metabolism, possibly in calcium deposition, making it liable to a condition like foetal rickets.

I thank the Superintendent of the Girls' School for allowing me to do the school medical inspection and for using the data. I thank the Superintendent and staff of the Clara Swain Hospital for their kind help in allowing me to observe, operate upon and follow up the case reported.

OSTEO-SARCOMA OF CERVICAL SPINE*

By ISRAR AHMAD, M.B., B.S.

Thomason Hospital, Agra

H. S., a Hindu male child, 11 years old, was admitted to hospital complaining of paralysis of both upper and lower limbs—duration two weeks.

The father stated that he injured his neck three months ago while playing. Three weeks later he developed paralysis, first of the left, and then of the right arm. Two weeks later the lower limbs were affected also. There was no difficulty in micturition or defæcation.

Examination revealed a hard, smooth, rounded swelling, the size of a large apple, occupying the front and left side of the neck and apparently growing from the cervical spine.

Quadriplegia was present.

X-ray examination showed a calcifying tumour growing from and destroying the left half of the 4th, 5th and 6th cervical vertebræ (see figure, plate II).

During his eight weeks' stay in hospital the tumour has grown visibly. After immobilization on a plaster of paris bed the paralysis in the limbs has improved and the patient can now move his upper limbs freely.

Operation being obviously out of the question, deep x-ray therapy was tried. Ten exposures

* Paper rearranged by J. A. S.

have been given so far without appreciable diminution in the size of the tumour.

I am very grateful to my chief, Major S. Ahmed, I.M.S., and also to Dr. H. N. Bhatt for taking the skiagram.

A CASE OF BRUCELLOSIS (ABORTUS FEVER)

By R. BHUYAN, L.M.P., L.T.M.

and

R. C. BARUA, L.M.P., L.T.M.

A. O. C. Hospital, Digboi, Assam

A PUNJABEE Hindu girl, aged 10½ years, was admitted to hospital on 26th July, 1946, with a history of fever for 3 days. The child developed fever on the day she arrived in Digboi from the Punjab where she had been staying for a period of 3 months on a holiday.

The temperature was of enteric type for first 3 weeks, then of undulant type; there was progressive splenic enlargement, and the bowels constipated at the beginning but regular after first 2 weeks. The child remained somewhat apathetic and dull when the temperature was high, otherwise looked fairly well. On the 12th week she developed painful swelling of left wrist joint, which subsided after 4 or 5 days with rest and fomentation. Headache, joint pain and poor appetite were the prominent symptoms.

Radiological examination of the chest on the 6th week showed no abnormality. Blood for malarial parasites, thick and thin films, was negative on several occasions. Widal and Weil-Felix reactions negative in a 1/250 dilution on the 10th and 15th day of illness. No tubercle bacilli were found after several examinations of 24 hours' sputum by concentrated method. Examination of fasting stomach contents for tubercle bacilli was also negative. Routine examinations of stool and urine were negative.

Blood picture during the 5th week of the illness was:—

W.B.C. .. 3,600 per c.mm.

R.B.C. .. 4,460,000 per c.mm.

Differential count:—

Eosino. .. Nil

Baso. .. Nil

Poly. .. 38 per cent

Lympho. .. 49 per cent

Large mono. .. 13 per cent

No L. D. bodies found in sternal marrow. On the finding of progressive enlargement of spleen a few bi-weekly diagnostic injections of urea stibamine were given up to a total of 0.75 gm., but no effect on the course of the disease was

apparent and consequently urea stibamine was discontinued. A course of 600,000 units of penicillin during the 6th week also did not appear beneficial.

On the 7th week agglutination tests and cultures for the *Brucella* organisms were done with the following results:—

$\frac{1}{25}$	$\frac{1}{50}$	$\frac{1}{125}$	$\frac{1}{250}$	$\frac{1}{1000}$	$\frac{1}{2000}$	$\frac{1}{5000}$
+	+	+	+	+	+	+

Concentrated agglutinable suspension (Standard) *Brucella abortus* was obtained from Central Military and Pathological Laboratory, Poona.

Primary blood culture on nutrient broth and subculture on agar media showed non-motile gram-negative cocco bacilli with the following biochemical reactions:—

Glucose	Maltose	Mannite	Lactose	Saccharose	Dulcitol
Nil	Nil	Nil	Nil	Nil	Nil

From the serological and cultural report the infection was diagnosed as brucellosis (abortus fever).

T.A.B. shocks (4 injections at intervals of 4 days) were given with no appreciable effect. A pentavalent antimony preparation (Fantarin—Glaxo) was also tried in doses of ½ c.c., 1 c.c. and 1½ c.c. on 3 consecutive days and 2 c.c. on the 5th day without any appreciable result.

The patient was discharged from hospital at the end of 13th week at the request of her parents. She became afebrile after two weeks' illness at home (i.e. after the 15th week of illness) and is now in perfect health, attending school and taking part in outdoor games.

Abortus fever is unknown as an indigenous disease in Assam and this was probably an imported case.

We wish to express our thanks to Dr. A. S. Prowse for his kind interest in the case and also to Mr. F. J. Valentine for kindly allowing us to publish this note.

DIAGNOSIS OF PRESUMPTIVE AMEBIC HEPATITIS IN A CHILD AGED TWO YEARS

By G. S. MOHAPATRA, M.B., B.S.

Civil Assistant Surgeon, Sub-Divisional Hospital, Bargarh, District Sambalpur

MANSON-BAHR in 'Manson's Tropical Diseases' reports an English girl of sixteen as his youngest patient and mentions the records of an Egyptian child of three months and some children of India of ten years of age suffering from hepatic amebiasis. Barring these records of children under ten years of age suffering from

amœbic infection of liver are rare. The following case is of interest from clinical point of view :—

'B', a female child of two years of a well-to-do family, came under my treatment on 5th September, 1946, with the complaint of fever of one and a half months' duration. The fever was of a hectic type and a rise was always accompanied with profuse sweats.

History of illness.—A fortnight before the child was first discovered to have rise of temperature in the evening she had loose motions with blood and mucus varying from 5 to 10 times a day. With ordinary treatment for colitis, the motions came to normal and the child began to have rises of temperature first in the evening—the morning temperature being normal. Gradually as the severity increased, the temperature became remittent in type—evening and night temperature going up to 102 or 103°F., morning temperature coming down to 99.5 or 100°F. Previous to the ailment the child was quite hale and hearty without any complaints whatsoever.

The child was emaciated with a sallow complexion and was anæmic. Tongue was clean and moist, lips dry and cyanotic. Pulse was rapid with low volume and disproportionately high in comparison with temperature. Abdominal examination revealed enlargement of liver downwards by two fingers below the right costal margin and upwards by about half an inch. On pressure over the right hypochondrium, tenderness in the region could be elicited but there was no sign or symptom of acute pain in the region. Otherwise the abdomen was quite healthy with no mass or tympanitis, neither the spleen was palpable. There was absence of painful or enlarged gland in the system. Examination of chest revealed crepitation and diminished breath sounds at the base of the right lung. There was no cough. Record of temperature for one week showed a definite tendency to tertian periodicity.

Stool showed undigested food particles, a few degenerated red cells and pus cells. No cysts of amœbæ could be seen in spite of repeated examinations.

Urine was clear with no deposit, reaction acid, specific gravity 1.016, no abnormal constituents detected.

Blood—total red cells 3,100,000 per c.mm., white cells 9,375 per c.mm., polymorphonuclears 68.5 per cent, lymphocytes 25 per cent, large mononuclears 5.5 per cent, eosinophils 1 per cent, basophils nil. Malaria parasites not detected in spite of repeated examinations. Hæmoglobin 55 per cent.

Treatment.—As is often seen with such cases in adults, the child had been saturated with quinine, mepacrine and atabrine (Bayer) successively by practitioners before she came under my treatment. This was probably due to the tertian periodicity of the fever and partially to the absence of other positive findings. Other

treatments given were salicylates with urotropine, vitamins and 'livergen'.

After close observation and necessary examinations I injected $\frac{1}{4}$ grain of emetine with 1/200 grain of strychnine in 1 c.c. of distilled water intramuscularly on 15th September, 1946, at 1 p.m. The night temperature on the date rose to 105.6°F. but it gradually came down till it touched normal in the morning. The injections were repeated daily for eight days, thus giving a total dose of 2 grains. During the whole course the temperature kept normal and the child remained with me for seven days more as the bowels were not moving quite well. Usual diet was slowly resumed and the child was discharged. Up till 20th November, 1946, the child was keeping normal with steady increase of weight and colour.

Points to note in the case were the absence of any œdema or pain in the region of liver (even though the child had temperature for one month and a half prior to starting treatment), leucocytosis, general toxæmia and cough.

MENINGOCOCCAL TOXÆMIA ACCOMPANYING MALARIAL INFECTION

By R. C. BARUA, D.M.P., L.T.M.

Assistant Medical Officer, A. O. C. Hospital, Digboi, Assam

A CASE was admitted to the hospital with history of continuous fever for 3 days. Fever started with chill, rigor, headache and pain all over the limbs.

On examination :—

Temperature	.. 103°F.
Pulse	.. 120. Very feeble and practically imperceptible.
Heart sounds	.. Very feeble and muffled.
B.P.	.. 80/40.
Spleen and liver	.. Not palpable.
Respiration rate	.. 22 per minute.
Lungs	.. Nothing abnormal could be detected.
Blood	.. M.T. rings were found.

The diagnosis of malaria was made and he was put on quinine (7½ grs.) thrice daily.

In the evening the temperature went up to 102.8°F. with profuse sweating all over the body and the patient became deeply cyanosed. Respiration rate rose to 30 per minute. Pulse was practically imperceptible.

Treatment.—Coramine, glucose, berin and other stimulants were given and he was put on continuous oxygen inhalation by a double-nasal catheter.

Next day (fifth day of fever).—The temperature was 100°F. The patient did not show any improvement of his general condition. He was deeply cyanosed, restless with profuse sweating all over the body but retained consciousness.

All the tendon reflexes were normal. No rigidity of neck muscles, and Kernig's sign was negative.

Heart sounds were muffled with a soft systolic murmur in the mitral area.

Lungs.—Coarse crepitations were heard over both the bases with increased V.R.

Blood.—The thick film showed a few malignant tertian rings.

Total white count—15,000 per c.cm.

Differential count :—

Eosinophils	..	Nil
Basophils	..	Nil
Myelocytes	..	Nil
Juvenile	..	3 per cent
Band	..	13 " "
Polymorphonuclears	68	" "
Lymphocytes	..	12 " "
Large mononuclears	3	" "

Nothing abnormal was detected in the stool examination. Urine showed a trace of albumin and triple and amorphous phosphates.

Treatment was continued with quinine bihydrochloride by the intramuscular and oral route and berin, glucose and other stimulants.

Sulphadiazine was also given on account of the lung condition.

Sixth day.—There was not much improvement and the same treatment was continued.

The lungs on both the bases showed signs of definite pneumonic condition.

On the fifth day of illness blood culture was done which showed gram-negative diplococci in blood agar after 48 hours' incubation and was confirmed by sugar fermentation test.

Fermentation was seen only in dextrose and maltose with acid production with no change in mannite, saccharose, dulcitol and lactose.

From the cultural report it was confirmed that the organism was meningococcus. Oral sulphadiazine was substituted by Dagenan sodium intravenously and sulphapyridine by the oral route.

Nasopharyngeal swab was taken before pushing Dagenan to see if there was any focus of infection and on culture showed some streptococcus of the non-hæmolytic type.

Eighth day.—The patient showed much improvement of his general condition, cyanosis, profuse sweating and all the symptoms of toxæmia disappeared gradually after 8 hours. He was all right after 48 hours of sulphapyridine treatment.

Lumbar puncture was not done in this case due to low blood pressure which was only 75/40.

Comments.—The case was definitely of a malignant tertian infection with pneumonic consolidation of both lungs and the septicæmic conditions which were produced later on were thought to be due to pneumococcal infection.

But the profound cyanosis, restlessness and profuse sweating all over the body and one of the most noteworthy symptoms was that the patient did not lose his consciousness, along with

this the positive blood culture report for meningococcus are of interest. In this connection reference may be made to an article entitled 'Meningococcal adrenal syndromes and lesions' by H. Stanley Banks and J. E. McCartney (*Lancet*, i, June 19, 1943, p. 771) and to an article entitled 'Bilateral adrenal hæmorrhage' by J. Edgar Morison (*Ibid.*, p. 800).

We suspect from the symptoms and other investigations that probably partial hæmorrhage into the gland occurred in this case.

My grateful thanks are due to Dr. A. S. Prowse, C.M.O., and Dr. R. H. P. Clarke, D.C.M.O., for valuable guidance and help, and to my colleague Dr. T. T. Das.

Therapeutic Notes

NOTES ON SOME REMEDIES

V. SULPHONAMIDES

I

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
T.D.D. (Wales), F.S.M.F.

Professor of Tropical Medicine, School of Tropical
Medicine, Calcutta

SINCE the epoch-making advance in chemotherapy was made in 1935 with the introduction of the sulphonamide group of drugs the literature on the subject has been so vast that it is difficult or almost impossible for the average practitioner to keep himself informed. Time therefore seems opportune to attempt a brief survey of the facts which have been evolved. Although lately somewhat overshadowed by penicillin, the sulphonamide drugs have still a wide field of application, particularly in our rural areas where the difficulty of storing penicillin and the need for frequent injections are real problems. In acute bacillary dysentery they have no rivals yet, and in certain other infections they are almost as good as penicillin.

Mode of Action

The action of sulphonamides upon susceptible micro-organisms is bacteriostatic, i.e. they prevent their growth and multiplication. Sulphonamides resemble chemically *p*-aminobenzoic acid which is an essential foodstuff for many bacteria. If the drug is presented to the bacterium in sufficient concentration the organism seizes upon it, but it is really no food. Its metabolism is retarded, it is unable to multiply and the battle is half won. Once the multiplication of bacteria is held in check, the leucocytes and other defence mechanisms of the body can come in and complete their destruction. Sulphonamides do not neutralize the bacterial toxins, nor do they stimulate the production of antibodies.

Organisms vary considerably in their susceptibility to the various drugs of the group, but this difference seems to be quantitative and not qualitative. For example, the fact that pneumococci and staphylococci respond better to sulphathiazole and sulphadiazine than to sulphanilamide is not due to their any specific action, but rather because there are more active compounds. In choosing a compound, however, not only its bacteriostatic power but also its physical and pharmacological properties have to be considered such as its absorption, excretion, solubility and toxic effects. Thus, sulphanilamide on account of its ready solubility is useful for local application; sulphadiazine produces particularly high blood concentration because of its slow excretion; sulphapyridine, though an excellent curative drug, frequently causes nausea and vomiting, while sulphaguanidine is effective against organisms in the lower part of the alimentary canal because it reaches this region in high concentration owing to its slow and incomplete absorption.

Absorption and Excretion

When taken by mouth, sulphonamides (except sulphaguanidine, succinyl-sulphathiazole and phthalyl-sulphathiazole) are more or less rapidly absorbed from the small intestine, depending on their solubility which is variable. The concentration in the blood reaches its maximum in three to four hours and then begins to fall owing to excretion which occurs almost entirely through the kidneys and which also varies with the drug used, but in most cases the greater part of it is eliminated within 24 hours, hence the need for giving it at regular intervals. With a dosage of 1 gm. given 4-hourly, the concentration may range from 5 to 10 mg. per 100 c.c. of blood or even higher and this is sufficient for most infections. Sulphaguanidine is only partly absorbed, while succinyl- and phthalyl-sulphathiazole are not absorbed except for trifling amounts; they are excreted in the faeces in high concentration.

After absorption the drug is found practically in all tissues and in all normal and pathological fluids of the body. In the liver part of it is conjugated with acetyl group, but the greater part remains free or unchanged. Both forms occur in the blood and urine. The acetylated part of the drug is therapeutically inactive. The amount of the drug which is acetylated varies with the different compounds and with the duration of its administration. The importance of the acetylated derivatives is that many of them are less soluble than the original compounds and that in passing out with the urine in which they appear in much higher concentration than in blood stream they tend to crystallize and so block the urinary passages. This is especially the case with sulphapyridine, sulphathiazole and sulphadiazine. It is therefore essential to ensure an adequate urinary outflow during sulphonamide therapy, especially if for any reason the flow is diminished (M.R.C., 1945).

Drugs in Common Use

Since the introduction of the sulphonamides into clinical medicine ten years ago, the therapeutic applications have greatly widened and a succession of new preparations has appeared, but only some 5 or 6 of them are in common use to-day. Sulphanilamide is the simplest member of the whole group and with it various chemical linkages have been prepared, and these possess curative action against bacterial infections insusceptible to sulphanilamide. None of them is perfect, each has its advantages and disadvantages which render it more suitable for some purposes than others. The following are briefly the chief properties of the common drugs :

Sulphanilamide is very soluble and is useful in streptococcal, meningococcal and coliform infections and also for local application. *Sulphacetamide*, also very soluble, is chiefly used for local application to delicate tissues such as the conjunctiva and in urinary infection. *Sulphapyridine*, though an efficient drug, has now been largely discontinued owing to high incidence of nausea and vomiting. *Sulphathiazole* is the most potent of sulphonamides and is effective against a wide range of infections. It is rapidly absorbed, and elimination is also rapid. Next to penicillin, it is the best of the sulphonamides for the treatment of staphylococcal infections, and though less soluble than sulphanilamide, it has greater bacteriostatic power when applied locally. *Sulphadiazine* has relatively low toxicity and has almost the same range of application as sulphathiazole. It is preferred in pneumococcal and meningococcal infections. As it is slowly absorbed from the intestine, treatment in acute cases should be initiated by an intravenous sulphonamide. Both *sulphamezathine* and *sulphamerazine* are derivatives of sulphadiazine but less toxic; the former is probably the least toxic of the sulphonamides except sulphacetamide but is rapidly excreted, while the latter being slowly excreted gives a higher and more constant blood level than any other sulphonamide in the same dosage, hence it may be administered in somewhat smaller doses. *Sulphaguanidine* and *succinyl-sulphathiazole* (*sulphasuxidine*) are used exclusively for bowel infection by the dysenteric group of organisms. The last one is of particular value in the treatment of dysentery carriers and in reducing the number of *B. coli* in the intestine. The newer drug, *phthalyl-sulphathiazole* (*sulphathalidine*), is said to be two to four times as effective as succinyl-sulphathiazole but reports on it are still scanty.

In the choice of drugs there is yet no unanimity, but the following list slightly modified from Anderson and Snodgrass (Dunlop *et al.*, 1946) will be found generally useful. When the nature of the infection is not known, the choice will rest between sulphathiazole, sulphadiazine and sulphamezathine.

Infection	1st choice	2nd choice
Streptococcal	Sulphanilamide	Sulphathiazole
Pneumococcal	Sulphadiazine	Sulphathiazole
	Sulphamezathine	
Meningococcal	Sulphadiazine	Sulphanilamide
Gonococcal	Sulphathiazole	Sulphadiazine
Staphylococcal	Sulphathiazole	..
	Sulphadiazine	
Dysenteric	Sulphaguanidine	..
	Sulphadiazine	
Coliform	Sulphanilamide	Sulphathiazole
Others (e.g. <i>Cl. welchii</i>).	Sulphadiazine	Sulphamezathine
	Sulphathiazole	

Methods of Administration and Dosage

1. *Oral administration.*—The drugs are usually supplied in tablet form in most cases, each tablet containing 0.5 gm. The tablets should be crushed and taken with 2 or 3 ounces of water, otherwise they may be passed out unabsorbed (Chaudhuri and Ghosh, 1945). In acute cases it is important to start treatment with a large initial dose (2 gm.) in order to raise the blood concentration as rapidly as possible and in very ill patients this or part of it (e.g. 1 gm.) should be given intravenously. Apart from this initial injection, the drug should, wherever possible, be given by mouth. It is continued in one gramme doses given every 4 hours till the temperature settles and there is clinical improvement, and then in smaller doses for a further 2 to 3 days. With each tablet a mixture containing sodium bicarbonate and sodium citrate, each 20 grains, is given. Each dose and its time of administration should be recorded on a chart. It must not be stopped too soon because of the risk of recurrence, nor should it be continued too long for fear of causing toxic symptoms, a course of 7 days being generally sufficient; only occasionally, as in meningitis and septicæmia, will it be necessary to extend this period. In comatose patients the drug may be given by a nasal tube, well diluted with water or milk. Children tolerate the drug better than adults.

If there is no definite improvement within 3 or 4 days of treatment, the blood level should be checked, and if it is below 3 to 4 mg. per 100 c.c., dosage should be increased or few doses given intravenously. On the other hand, if it is adequate, the infecting organism is probably insensitive. This insensitivity may be absolute when it is useless to continue the drug, or relative when bigger dose or a change to a more active compound may be tried. When blood tests cannot be carried out it is better to discontinue the drug if no response is obtained within the fourth or fifth day of the drug.

The following schedule of dosage is recommended for Indian patients of average build and is applicable to all the drugs except sulphaguanidine and succinyl- and phthalyl-sulphathiazole. The table is intended for general guidance and the dosage may have to be modified to suit the individual patient or the special

properties of the drug given. When the infection is very heavy, the individual doses may be increased especially during the first 24 hours of treatment.

Age group, years	Initial dose	Four-hourly dose
0-3	0.5 gm.	0.25 gm.
4-10	1.0 "	0.5 "
11-15	1.5 "	0.75 "
Over 15	2.0 "	1.0 "

The three drugs solely used in intestinal infections are always given by mouth. Ordinary daily doses of sulphaguanidine and succinyl-sulphathiazole are 6 to 12 gm. for adults and 3 to 6 gm. for infants and children, while in the case of phthalyl-sulphathiazole 3 to 4 gm. have been found to be sufficient daily dose.

In subacute infections it is not necessary to give the intravenous injection and the dose is slightly reduced though some clinicians use the same amount as in acute cases. In urinary infections smaller doses (3 to 4 gm. a day) need be given than in general infections since the concentrations of the drugs in the urine are much higher than in the blood.

2. *Parenteral administration.*—This is indicated when it is desired to rapidly raise the blood concentration or when the oral route is impracticable. Intravenous injections are to be preferred and they may have to be repeated in case of vomiting or sustained coma. The sodium salts of the drugs which are readily soluble in water are used. These solutions, being alkaline, are irritant to the tissues and liable to cause necrosis but can safely be injected intravenously, provided care is taken not to let the fluid escape outside the vein. The contents of an ampoule (1.0 gm.) are drawn into a syringe containing 10 c.c. of either sterilized distilled water or normal saline and are injected very slowly into a vein. Alternately, one of the soluble forms of sulphanilamide available in the market may be used, e.g. sulphanilamide L.S.F. and solu-septasine; as these are non-irritant to the tissues they can be injected subcutaneously, intramuscularly or intravenously, but they are less potent. The sodium salts must not be injected subcutaneously or intrathecally.

When oral or intravenous routes are impossible as in dangerously ill patients with collapsed or very small veins, intramuscular injection is permissible; it must be deep and well away from important nerves as these are particularly liable to damage from the highly alkaline solution. The vastus externus is the muscle recommended, and the injections must be spaced at distances of at least 3 inches from one another.

3. *Local application.*—Sulphanilamide and sulphathiazole are the two substances that have been mostly used in skin diseases, burns and wounds or in peritonitis. The tablets as used for oral administration must not be used for this

purpose, but pure sterile powder in ampoules or special containers is available in the market.

Sulphonamide Resistance

An important cause for lack of response in treatment is the development of resistance of the bacteria to the action of the sulphonamides. This occurs when small and ineffective doses are given for prolonged period, particularly in infections due to pneumococci, gonococci, streptococci, *B. coli* and dysentery bacilli. When it occurs, it extends to all compounds of the group, although an organism which resists the weaker action of sulphanilamide may succumb to a more active substitute such as sulphathiazole. Once a strain has become unusually resistant, it can maintain its resistance for long periods and be propagated with the virulence of the parent strains. Apart from this acquired resistance, strains are occasionally met with which are naturally insensitive to the sulphonamides. But it should be remembered that in sulphonamide therapy the patient's resistance counts as much as the drug and the bacterium and if it is poor, then the drug may well fail.

When sulphonamide resistance does occur, there will be absence of the expected clinical response and this may be confirmed by laboratory tests. Every effort should be made to avoid producing it by faulty therapy and intensive courses of treatment should be given from the beginning except for special purposes, as then the development of drug resistance is unlikely. Too gloomy a view should not be taken of the difficulties which sulphonamide resistance may cause, the great majority of infections still respond to the drug and luckily the resistance does not extend to the bacteriostatic compounds of a different type such as penicillin.

Incompatibles

The inhibitory action of sulphonamides on bacterial growth can be neutralized by small quantities of *p*-aminobenzoic acid and a number of local anaesthetics chemically allied to it such as procaine, benzocaine and orthocaine. This has obvious clinical application in infected cases under sulphonamide therapy and requiring local anaesthetic. While occasional small doses seem to have no effect on the therapeutic value, massive or repeated doses of procaine may weaken the effect of the drug and may even be dangerous especially in the early stages of the therapy and more particularly in those cases not receiving intensive treatment. de Waal *et al.* (1942) suggest the use of not more than 10 c.c. of a 3 per cent solution of procaine (or correspondingly greater amounts of a weaker solution)—a dose which should be sufficient in minor surgical operation. When a large amount of a local anaesthetic is required under these conditions, one of the drugs not allied to *p*-aminobenzoic acid like stovaine, nupercaine and eucaine should be used.

Substances antagonistic to sulphonamides also occur in pus and necrotic tissue, consequently

the drugs exert less effect than usual if they are applied to wounds containing pus or sloughs. In the early days of sulphonamide therapy it was customary to forbid sulphur-containing food and drugs concurrently as predisposing to the development of cyanosis, but this view has been shown to be unfounded. Sulphonamides and quinine should not be given simultaneously as the combination is said to be toxic. Sulphonamides and mepacrine may, however, be given at the same time.

Toxic Effects

These effects are not common, considering the widespread use of sulphonamides. The following are the more important of them :—

1. *Headache, nausea, vomiting or malaise.*—These are early symptoms but usually of little importance. Restlessness and inability to concentrate may also be present. Vomiting is more frequent with sulphapyridine and rare with sulphathiazole or sulphadiazine. Should it persist, the drug should be changed or administered parenterally.

2. *Cyanosis.*—This occurs more often with sulphanilamide, and is usually due to the formation of methæmoglobin in the blood. It is of no clinical importance except in anæmic patients, but if it is causing alarm to the patient's friends, it can be cured in 15 to 30 minutes by intravenous administration of 10 c.c.m. of 1 per cent solution of methylene blue, or in 3 to 4 hours by giving 200 mg. by mouth. Thionin stain can be used in the same way. A very rare but dangerous form is that caused by sulphæmoglobin, it is unaffected by methylene blue, and may persist for several weeks.

3. *Hypersensitivity.*—The most important reactions are skin rashes and drug fever and seem to be due to some kind of acquired hypersensitivity developed during a previous course of treatment or during the earlier stages of the same treatment. Sulphathiazole seems especially liable to produce these manifestations. The most common form of *skin rashes* is a discrete papular erythematous rash, often accompanied by fever and severe itching. It appears about the tenth day, but in patients who have previously had the drugs it may appear much earlier, sometimes within a few hours of the first dose. The rash clears up quickly with the stoppage of the drug, but as it may be a prelude to more serious complications, a leucocyte count should be made. Sensitivity may also develop after continued long application of sulphonamide ointments for skin infections, leading to both local and general reactions such as eczema, pruritus and fever.

Drug fever may appear in 2 or 3 ways. The original pyrexia may be prolonged or it may quickly subside followed after a day or two by its reappearance, but by far the most common form of fever occurs later, *i.e.* about the tenth day and is seen when sulphonamide is being given for the first time. The temperature rises to 102°F.

or more, frequently associated with rigors, and there may be vomiting and pain and swelling of joints with polymorphonuclear leucocytosis. The difficulty is to exclude recrudescence or relapse of the original infection. Drug fever should be suspected when (1) a rise of temperature cannot be adequately explained by the physical signs, (2) there is already definite improvement in the general clinical condition, and (3) omission of the drug brings about a fall in temperature though not always abruptly. On the other hand, a rise of temperature occurring a few days after stopping the drug is usually due to a recrudescence of the infection.

Generally speaking, these complications are encountered most frequently when therapy is prolonged but although personal idiosyncrasy seems to play a part in their production prevention is assisted by not continuing the drug longer than is necessary, usually stopping the therapy by the seventh day in all but exceptional cases. When they do occur the best course is to stop the drug, but if the complication arises early and in the form of fever only, a careful clinical survey of the case is needed before it is stopped prematurely. As a preventive, it has been recommended that a patient who has previously suffered from hypersensitivity should, if he is to receive sulphonamide again, be given a different compound from the one used during the first course.

4. *Blood changes.*—A minor degree of anæmia is common but is more often due to the disease than the drug. The changes may manifest as purpura, aplastic and acute hæmolytic anæmia or agranulocytosis, the latter being the commonest of these rare complications. The occurrence of unexplained fever, slight jaundice or a sore throat should arouse suspicion. Acute hæmolytic anæmia is a dangerous complication and the symptoms may set in at alarming speed. It has been reported most often after sulphanilamide and more frequently in children than in adults. Agranulocytosis is another serious complication which seems to depend more on the duration of treatment (it is rare before the fourteenth day of therapy) than on the total dosage. Purpura in association with this condition is of grave import.

The occurrence of these blood changes is an absolute indication for stopping the drugs. Although careless use of the drugs for long periods predispose to them, prevention is not always easy owing to personal idiosyncrasy in some patients. When massive doses are given or when treatment is continued for more than seven or eight days the hæmoglobin and white blood cells should be examined regularly. If the hæmoglobin falls below 40 per cent or the total white cell count is under 3,000 per c.mm., treatment should be immediately discontinued. When these complications develop necessary appropriate treatment should be given.

5. *Renal irritation and urinary suppression.*—As already mentioned, the less soluble sulphona-

mides and their acetyl derivatives are liable to deposit crystals which may cause irritation and even go to the extent of blocking the urinary passages. It is therefore essential to give ample fluids so as to secure a good flow of urine; as a general rule, a pint of fluid should be given for each gramme of the drug up to six pints a day, the aim being to maintain an urinary output of about 50 ounces in an adult. It is also desirable to keep the urine alkaline by giving a mixture of sodium bicarbonate and sodium citrate as already recommended, since the sulphonamides and their acetyl derivatives are more soluble in alkaline than in acid urine, though this is not always easy with the highly acid urine of the febrile states. The urine should be inspected (for suspicious blood) and measured daily and whenever possible it should be examined microscopically on the third or fourth day. The finding of crystals or blood is no contraindication to the continuation of the therapy, but it is a warning for caution.

If renal pain, macroscopic hæmaturia or oliguria occurs, the drug should be stopped at once and fluids by mouth must be forced and intravenous injection of one pint of saline and glucose should be given. But a large fluid intake is harmful if the urinary flow is not established within 4 to 6 hours as it causes œdema of the lungs. Heat should be applied to the loins. In most cases these measures are sufficient, but if anuria persists for 12 hours or if oliguria (less than about 15 oz.) persists for 24 hours, ureteric catheterization and lavage or other surgical procedures will have to be carried out, and for this a surgical specialist should be consulted. But before doing this it is worth applying massage to the lower end of the ureter by rectum, as the blockage often occurs in this part of the urinary passage. Flynn (1943) has successfully treated some cases of sulphonamide anuria in this way. 'With the patient in the knee-elbow position, the ureteric openings into the bladder (three-quarter of an inch to 1½ inches above and to the outer side of the prostate) are massaged per rectum. The ureters enter the bladder at a point one-third of the way up the seminal vesicle on the outer side, and crystals are commonly formed at this site. Massage over the kidneys and ureters is then performed from above downward with the patient lying on the back; two or three minutes per side is usually sufficient'.

[To be continued.]

JANUARY

THE IRRESISTIBLE IMPULSE

Freedom from criminal responsibility.—Such a freedom in English law is accorded under the McNaughten Rules. These rules are incorporated in Indian law also.

The rules were framed after the McNaughten trial in 1843 and have not been revised (an attempt in 1924 failed). McNaughten had killed a Mr. Drummond, a Secretary of Sir Robert Peel, the then Prime Minister of England. He had mistaken the Secretary for the Prime Minister himself for whom he had lain in wait. He had been acquitted on the medical evidence of insanity. The acquittal had not been received favourably by the public. The House of Lords then had put certain questions to a full bench of 14 of Her Majesty's judges. Their Lordships' answers became known as the McNaughten Rules.

According to the rules, if a person because of his disordered mental state was unable to distinguish between right and wrong at the time of doing an act which would have been criminal when done by a mentally normal person, he is not guilty. He has no criminal responsibility.

Diminished responsibility.—Can a person, instead of having no responsibility, have a diminished responsibility? Medically, no reasonable doubts can be entertained against such a possibility. Medical profession recognizes disorders of behaviours, falling short of certifiable insanity, in certain diseases. Medical boards disqualify for state service persons suffering from such diseases. Recently in Scotland such a defence has been admitted (Smith, 1943). 'In the case of *Rex v. Savage*, Lord Alness stated that the law had come to recognize those who, while they may not merit the description of being insane, were nevertheless in a condition as to reduce the quality of their act from murder to culpable homicide' (Glaister, 1942).

Irresistible impulse.—Another grade in the downward path of a person's volition is the domination by an irresistible impulse. Is a person, at times, unable to control his doing of a wrongful or criminal act (which he knows to be wrong and criminal)? The English law is definitely against such a possibility or at least against giving the wrongdoer an advantage under it. 'At the hearing of the appeal of *Kopsch*, the Lord Chief Justice said that the fantastic theory of uncontrollable impulse was not yet part of the criminal law, and it was to be hoped that the time was very far distant when it would be made so' (Glaister, *loc. cit.*).

The same view is held in Canada (Meredith, 1946) and probably elsewhere in the British Empire.

On the other hand, some 17 States in U.S.A. (Werhofin, quoted by Meredith, *loc. cit.*) while retaining the original right-and-wrong test admit the defence of irresistible impulse.

It should be emphasized that the McNaughten Rules were framed in the last century before psychiatry was born, that insanity can impair emotion without altering (appreciably) intellect and that an unaltered intellect can be governed by an impaired will. When a plea of insanity is advanced in a capital charge the expert should state these facts (together with those of altered behaviours, falling short of certifiable insanity, if necessary) for the benefit of the jury. Even if the plea fails, due to a rigid adherence to the McNaughten Rules by the judge, the accused will receive the benefit of another examination by another expert after conviction but before execution which may thus be barred by the finding by the expert (Yellowlees, 1946).

The real difficulty in the recognition of the existence of the irresistible impulse appears to be one of proof: How is it to be decided whether the impulse was irresistible or simply unresisted? This should be a matter of evidence, ordinary as well as expert. The latest developments in electro-encephalography may help.

In India the plea of a fit of impulsive insanity was considered in the case of *Matin Ali* (*Leader*, 25th September, 1933; quoted by Modi, 1943). This young man with a friend engaged a taxi from Nagpur to Chindwara, while returning shot dead the owner and the cleaner, and absconded. He was arrested on the fourth day of the occurrence. For this double murder he was sentenced to transportation for life by the Sessions Judge of Chindwara. On appeal the Judicial Commissioner observed that although the acts did not fall under S.84 I.P.C. (Act of a person of unsound mind) but under S. 302 I.P.C. (Murder), yet they deserved indulgent considerations, as they were committed in a fit of impulsive insanity, without motive or premeditation, by a young man who belonged to a good family and had received higher education.

Resistible impulse made irresistible by unusually strong incitement.—Such a transformation undoubtedly occurs when political slogans and fanatical war-cries turn respectable, law-abiding and God-fearing citizens into hooligans and fratrieides. This point deserves special consideration in India where criminals, unlike their homologues in Europe, are known to be impulsive rather than cold-blooded designers of antisocial activities (Owens, 1935).

Resistible impulse made irresistible by a lowered resistance of the body, by age.—That due to advances in nutrition, therapeutics and economics the expectation of life has increased after World War I is well known. As a result more elderly persons are alive to-day than

ever before in history. Some of them are committing crimes for the first time. Should they be punished as an ordinary young offender is punished or should a senile offender be recognized as the juvenile offender has been recognized?

It is admitted that even when the concession for bodily defects and lack of suitable social surroundings has been made a fair number of the offenders may turn out to be just wicked old men who are misusing their knowledge of the world and mankind, and their leisure. Such men are known to mythology and do not appear to have been assets to their communities, in the light of to-day. Many, however, will be spared the indignities from which age should be exempt and, when corrected, will give the society in return, as reformed elders, the benefit of their experience of a long life in a busy world.

Immunity from punishment of the impulsive antisocial elements not advocated.—Even acknowledgedly insane inmates of lunatic asylums are not altogether immune from punishments which are provided for in the rules of the asylums. All antisocial elements should be collected, detained and corrected. Some of them may even be liquidated by euthanasia, if necessary, as a matter of expediency. A distinction, however, must be made between the hopeless and the helpless.

WORLD HEALTH ORGANIZATION

SECOND SESSION OF THE INTERIM COMMISSION,
GENEVA, 4TH TO 13TH NOVEMBER, 1946

(From a press communique issued by the United Nations, dated Geneva, 7th November, 1946)

'The attainment by all peoples of the highest possible level of health' is the objective assigned to the World Health Organization by its Constitution. The importance of this objective scarcely calls for proof; were one required, it could be found in the speed with which the new world organization is taking shape and

the fact that many personalities in the first ranks of science and health administration are devoting their efforts to it. It was in June-July of this year that more than 60 States who took part in the World Health Conference pledged themselves to create a new organization which would take over all health activities of other existing international organizations. The aim is to bring about a single organization whose task it will be to foster every activity which might contribute to the improvement and maintenance of health, to encourage the efforts each Government is making on behalf of its own nationals, to co-ordinate their efforts, and to enable scientists as well as public health officials to profit from experience acquired in other countries.

The forerunners

The necessity for an international organization of this kind has long been recognized. As long ago as 1907 the International Public Health Office was created, having its seat in Paris, with the task of preparing and administering international quarantine conventions.

At the end of the first World War the League of Nations in its turn established its Health Organization to fight the formidable epidemics of typhus fever, relapsing fever, cholera and smallpox then ravaging eastern Europe. A sanitary cordon established on Poland's eastern boundaries and technical help furnished to threatened countries protected central and western Europe from this scourge. During the years that followed, this Organization, with its headquarters at Geneva, helped at their request the health authorities of certain countries to improve and modernize their services with the collaboration of international experts and the advice of *ad hoc* committees. In concentrating and co-ordinating the work of scientists the world over, the technical committees of the League of Nations made their contribution to the progress of medical science and its practical application to the prevention of disease. Whether in the field of epidemiology, standardization of biological products, tuberculosis, cancer, typhus fever, malaria, sleeping-sickness, child welfare, nutrition, rural hygiene and many other subjects, the importance of their work is denied by none.

During the second World War, foreseeing the possibility of new epidemics in its aftermath, the United Nations entrusted its Relief and Rehabilitation Association (UNRRA) with the task of aiding devastated countries in their anti-epidemic struggle and in the reorganization of their national public health services.

Their amalgamation

At its first session held in February 1946, the Economic and Social Council decided on the fusion of these three international organizations dealing with public health into a new World Health Organization whose charter was drawn up subsequently by the International Health Conference at New York. This Conference decided on the dissolution of the International Public Health Office (Office international d'Hygiène publique) and on the taking over by its new World Health Organization of the health activities of both UNRRA and the League of Nations. Pending ratification of the Final Acts it had drawn up and adopted, the Conference established an Interim Commission which would take the necessary steps to start the Organization—which is to be a specialized agency of the United Nations—working. The first session of the Interim Commission took place in New York (immediately after the Conference) and presented the Economic and Social Council with a report which was examined and approved; the second session of the Commission was held in Geneva from 4th to 13th November, to find a solution of those administrative and financial problems which could then be settled.

The second session

With Dr. Andrija Stampar (Yugoslavia), Rector of Zagreb University and Chairman of the Economic and Social Council of the United Nations, in the Chair, the Interim Commission set up working committees on administration and finance, on relations with other

organizations, and on epidemiological and quarantine problems. The Chairmen of these committees were, respectively, Dr. van den Berg, Director-General of Public Health of the Netherlands, Dr. Aly Tewfik Chouha Pacha, Under-Secretary of State in the Egyptian Ministry of Public Health, and Dr. Mackenzie, Senior Medical Officer of the Ministry of Health of the United Kingdom. Of the work accomplished by these committees, which was approved in plenary session, the following decisions should be recorded:

Various agreements were drawn up to establish relations and methods of liaison with the qualified organs of the United Nations, in connection with WHO's situation as a specialized agency (reciprocal representation at meetings, exchange of information, implementing of recommendations, mutual assistance in different fields, e.g. public relations, publications, etc.). The World Health Organization will report more particularly to the Economic and Social Council, and may be entrusted with items interesting the Security Council and the Trusteeship Council; the Permanent Court of International Justice can also apply to it for its opinion.

Principles of liaison and co-operation between WHO and other specialized agencies have, moreover, also been adopted. Collaboration is for instance envisaged with the International Labour Office (ILO), the Food and Agriculture Organization of the United Nations Educational, Scientific and Cultural Organization (UNESCO), and the Provisional International Civil Aviation Organization (PICA). Steps have also been taken to establish relations with various non-governmental national or international organizations interested in public health. Finally negotiations are under way for the integration of the Pan-American Sanitary Organization with the World Health Organization.

Budget

The budget for the end of 1946 was reviewed, the credit of \$300,000 being far from exhausted. The budget for 1947 amounts to \$1 million, to which sum should be added the figure of \$1 and a half million gifted by UNRRA for the continuation by WHO of its health work. While taking into account these financial assets and the degree of urgency of each task, the Interim Commission will at once tackle the effective work which should lead to the realization of the aim it has set itself to achieve. This programme of work includes the following points:—

The coming tasks

As regards epidemiological information, the work hitherto performed by the League of Nations has already been taken over and that of the International Public Health Office (Office international d'Hygiène publique) and of UNRRA will be absorbed in less than a month's time. The setting up of a Quarantine Committee has been decided upon, which is to consist of nine members, whose task it will be to supervise the application of the international sanitary conventions. It can count upon the advice of a sub-committee of seven experts on yellow fever.

For the standardization of sera and certain drugs a Nuclear Committee of Experts on Biological Standardization will study, pending the setting up of a larger committee, which are the most urgent problems to be taken up.

From the beginning of next year UNRRA's health activities will be taken over; notably as regards its work against malaria and tuberculosis in Greece, the training of local personnel in sanitation and health work in Ethiopia and China, and various other projects such as the granting of fellowships and the despatch of expert missions to countries with special needs.

An expert committee will deal with the revision of the International Nomenclature of Diseases. A committee of experts with technical knowledge of the pharmacology of narcotics and drug addiction will be

set up to advise the Commission on any question which may be submitted to it by the Drug Supervisory Body. The creation of a technical preparatory committee on malaria has been decided on. Various other problems were touched upon as calling for study at a later date; technical formation of sanitary personnel, organization of the health services of certain countries, methods of combating venereal disease and post-vaccinal encephalitis.

The Commission also approved the programme drawn up for publications.

The headquarters of WHO

The question of the permanent seat of WHO was discussed, as a result of which a committee of five members (Canada, Egypt, India, Mexico and Norway) was entrusted with the task of examining the position and reporting back to the Interim Commission which will, in turn, refer the question to the forthcoming World Health Assembly, the date of which has not yet been decided upon but will probably meet next summer as it is likely that by that time the requisite number of ratifications will have been received.

Until then the Executive Secretary and his staff will have to carry out the work entailed by the decisions taken at present and prepare for the next session of the Interim Commission, which is to take place in Geneva on 31st March, 1947. A decision regarding the headquarters of the Interim Commission was made in the following terms:

'The Interim Commission:

(1) Takes note of the establishment of a headquarters office in New York capable of assuring indispensable liaison with the United Nations, and the fulfilment of other functions of the Interim Commission;

(2) Authorizes its Executive Secretary to set up an office in Geneva in order to facilitate the activities of the Interim Commission;

(3) Authorizes its Executive Secretary, in agreement with the Chairman of the Interim Commission, to set up offices in other places if it will be indispensable for other activities.'

Conclusion

As can be seen, the second session of the Interim Commission has in large measure completed the preparatory work and a stride has been made towards the effective realization of the aims of WHO.

In conclusion, we would like to mention the names of the personalities who took part in the work of the Commission. It will be seen from their qualifications that in most cases they are members of Governments or high officials directing the health services of their countries. The States Members of the Interim Commission were represented as follows:

Dr. G. M. Redshaw, Chief Medical Officer for Australia; Dr. G. H. de Paula Souza, Director of the Public Health Faculty of Brazil; Dr. Brooke Claxton, Minister of National Health and Welfare of Canada, assisted by Dr. T. C. Routley; Dr. Sze-ming Sze, Resident Representative in Washington of the National Health Administration of China; Dr. Aly Tewfik Chouha Pacha, Under-Secretary of State at the Ministry of Public Health, Cairo, Egypt; Dr. A. Cavaillon, Secretary-General of the Ministry of Public Health, France, assisted by Drs. L. Bernard and H. Y. Santer; Major O. Mani, Deputy, Public Health Commission, New Delhi, India; Dr. J. Togba, Department of State, Liberia; Dr. M. Martinez-Baez, Chief Health Officer, Mexico; Dr. C. van den Berg, Director-General of Public Health, Netherlands, assisted by Dr. W. A. Timmerman, Director of the National Institute of Public Health; Dr. K. Evang, Director-General of Public Health in Norway; Dr. M. Mackenzie, Senior Medical Officer, Ministry of Health, and Dr. W. H. Kaantze, Chief Medical Adviser at the Colonial Office, United Kingdom; Surgeon-General T. Parran, Director of the Public Health Service of the U.S., assisted by Dr. H. van Zile Hyde; Dr. F. G. Krotkov, Deputy Minister of Public Health of the U.S.S.R.; Drs. A. Gabaldon and D. Curiel, respectively Chief of the

Malaria Division and Chief of the Division of Epidemiology and Vital Statistics of the Ministry of Health and Social Welfare; and Dr. A. Stampar, Rector of Zagreb University, assisted by Dr. D. Juzbasic, Professor at the Medical Institute of Skopljje, Yugoslavia.

International organizations were represented by Mr. G. E. Yates, Secretary to ECOSOC and Dr. J. Lucas of the Trusteeship Division, for the United Nations; Dr. M. T. Morgan, President of the Permanent Committee and Dr. L. Gaud, President of the Commission on Finance and Transfer, for the International Public Health Office (Office international d'Hygiène publique); Dr. N. Goodman, Director of the European Health Division, for UNRRA, and Dr. A. A. Moll, Secretary, for the Pan-American Sanitary Bureau. The Secretariat of the Interim Commission was represented by its Executive Secretary, Dr. G. Brock Chisholm, former Deputy Minister of Health for Canada, and Dr. Y. Biraud, Deputy Executive Secretary, former head of the Epidemiological Intelligence Service of the League of Nations.

CENTENARY OF ANÆSTHESIA CELEBRATED IN AUSTRALIA

MUSEUM OPENED IN MELBOURNE

By LEN BARKER

(Abstracted from Release No. MNL/110 offered by the Public Relations Officer, Australian High Commissioner's Office, New Delhi.)

THE 100th anniversary of the first successful public use of a general anæsthetic was celebrated in Melbourne (Australia) by the opening of a museum of anæsthesia at Melbourne University. The only other known museums of its kind are in New York and London.

Established by the Australian Society of Anæsthetists, the museum was opened on 16th October, 1946. It is not intended to be merely an exhibition of relics, but a modern school of instruction where the history of anæsthesia is traced and the student of anæsthesia is shown models or replicas of the different instruments and drugs used since the technique was discovered, and the reasons for their subsequent abandonment.

The founders of the museum have taken great pains to obtain many original or models of instruments invented after Dr. W. T. G. Morton, a Boston dentist, first publicly demonstrated his anæsthesia technique. The collection naturally begins with a model of Dr. Morton's instrument, a glass bowl with a beer cask tap fitted on the side. Ether was introduced to the bowl through a wide aperture which also served as an air inlet. When the end of the tap was inserted in the patient's mouth, he breathed ether. The flow of air through the bowl was uncontrolled, however, so the amount of ether absorbed by the patient could not be adequately gauged.

Nevertheless, it was a revolutionary step from earlier crude methods of analgesia, when doctors used alcohol and force to subdue patients undergoing operations.

Just as primitive were methods in vogue during the days of Nelson. The victim was plied with rum in which tobacco had been soaked. The rum took the sharp edge off pain and the tobacco made the patient so sick that he relaxed, and did not offer much opposition to the surgeon.

Judged by the general progress since those days, methods of anæsthesia in use in some Continental countries as late as the outbreak of World War II were astoundingly backward.

Instruments captured by the Australian army from the Italians in Tobruk, and now on view in Melbourne's museum of anæsthesia, give some indication of the antiquated practices used in the Italian army.

Perhaps the most primitive of them is a wooden mouth screw used to open the mouth to prevent asphyxiation during anæsthesia. The point of the screw was thrust between the teeth and twisted!

An ether mask described by the museum as the 'worst in the world' is another archaic instrument captured from the Italians. It is a large mask very similar to a baseball mask with an oil silk cover. Ether was poured through a small hole in the top and the mask's design ensured that little oxygen reached the patient, resulting in anæsthesia by asphyxiation as well as drugs.

Anæsthesia as a speciality in Australia began in the early 1900's, although ether was in use in Australian cities one year after Morton successfully displayed his method.

Even earlier, Dr. E. H. Embley, an Australian general practitioner with a flair for experimental work, was concentrating on anæsthesia research.

In 1900 the safety of chloroform compared to other anæsthetics was a contentious question, which was studied by a commission sponsored by the Nizam of Hyderabad in 1889. It found that the danger of chloroform was that it caused failure of respiration. Embley investigated the matter in the Physiology School of Melbourne University, and published his findings in 1902. He showed that the main danger of chloroform was in its effect upon the heart.

While not all of Embley's work has survived 40 years of further research, it was a worthy contribution to anæsthesia, and stimulated world-wide interest, besides marking the beginnings of serious anæsthesia research in Australia.

A surviving contemporary of Dr. Embley, and perhaps the first Australian specialist in anæsthesia, is Dr. R. W. Hornabrook, who is still living in Melbourne, though long retired from practice.

He is known as a pioneer of 'open' methods of anæsthesia with ether and ethyl chloride. 'Closed' methods did not permit a free flow of oxygen, so bordered on being asphyxia rather than anæsthesia.

Dr. Hornabrook was followed by Dr. F. W. Green, also of Melbourne, who died in 1937. He played a major part in the introduction of endo-tracheal anæsthesia into Australia and was of great assistance to later specialists in that branch of medicine.

Until 1930, there were very few specialist anæsthetists in Australia, and this helped to retard Australian discoveries in anæsthetics. Previously Australia had been well behind in the application of latest overseas techniques.

Gas oxygen anæsthesia, for instance, had outgrown experimental stages in the United States by 1911, and in England by 1916, but it did not arrive in Australia till 1923.

But since 1930 the number of specialists has mounted steadily. To-day they are keeping abreast of latest overseas techniques, and new methods are practised within weeks of their publication abroad.

While American and British anæsthetists have been organized since the end of the last century, the Australian Society of Anæsthetists was created at a medical congress in Hobart (Tasmania) in 1934. A consciousness of their 'youth' has spurred Australian anæsthetists, and they are doubly anxious to make up for lost time.

Modern research into anæsthetics demands team work not only between doctors, but also pharmacologists, manufacturing chemists and engineers. The industrial gas and engineering industries of Australia have kept step with needs of modern anæsthesia. When the Australian army took to the field in 1939, it was equipped with anæsthesia gases and apparatus of Australian manufacture and design. To-day these industries are exporting the gases and the apparatus for their administration.

With the co-operation of Australian gas and engineering manufacturers and the various branches of science, Australian anæsthetists need no longer be able exponents of the ideas of others, but creators who will be able to follow the example set by Embley, and join other Australian scientists who have elevated Australia to world rank in scientific and industrial fields.

Public Health Section

A DIETETIC SURVEY OF GUJARATI MEDICAL STUDENTS

By J. D. PATHAK, B.Sc., M.D. (Bom.)

Department of Physiology, B. J. Medical College, Ahmedabad

To know if the diet of the students of the medical hostel, Ahmedabad, was adequate, a dietetic survey was undertaken for a period of 10 days in September 1946. There are three messes in the hostel, two strictly vegetarian and the third 'cosmopolitan' catering for mixed diet. The total number of members at the time of inquiry was 91 out of which 85 were Gujarati Hindus and six up-country Hindus. The latter were members of non-vegetarian club. There were 45 members in one vegetarian mess and 25 in the other. Most of the students were between 21 and 24 years of age.

They usually take a small breakfast and two principal meals at noon and in the evening, and a cup of tea in the afternoon. Wheat, maize, rice, pulses, vegetables and milk are the principal items of their diet. Their noon dishes consist of rice, dal, chapati, some pulse and vegetables. Occasionally they take 'farsan', i.e. fried articles as 'bhajis', etc. In the evening they usually take fried cakes or chapatis, vegetables and milk and sometimes rice and dal or 'khichari' in addition.

The items of food supplied for cooking were weighed every day for the 10 days of the inquiry. The cooked food left in the messes after the members had taken the meals was accounted for but the small amount left in their dishes after meals could not be determined and hence have not been deducted in the tables. In the process of cooking the water in which rice was boiled was partly discarded. Such a procedure is likely to result in some loss of vitamins especially B₁. The water in which vegetables were cooked was not thrown away. Fried articles were consumed often. The process of frying involves loss of fat lowering the caloric value besides rendering the articles less digestible. Due to the conditions existing at the time of inquiry fresh vegetables, meat and fish were difficult to get. In normal times, however, the vegetables are consumed in sufficiency.

The results of the survey are shown in tables I and II.

This is an estimate of 'gross food values'. In considering the 'net' figures therefore more than 10 per cent should be deducted. The food values have been taken from the tables prepared by Aykroyd (1941).

Discussion.—Gujarati diet is defective in many aspects. The boys in the hostel take a typical middle-class Gujarati diet. Their caloric intake is a little below than that required for their age and activity. The diet also lacks in 'protective' foods. It is very poor in animal proteins only 6.7 gm. per day. The fats, carbohydrates and iron are consumed sufficiently whereas calcium and vitamins A and C are taken inadequately.

They keep average good health but are poorly built compared to the European, Sikh or Pathan standards. Sore throat with occasional ulcers in the mouth and common cold are their most common complaints. None of the students showed signs of a manifest deficiency disease.

Very few dietetic surveys of Gujaratis have been made so far. Professor Kanga in 1934 had estimated the diet of Gujarat College Hostel Club for a week. The other systematic survey carried out on a fairly large scale in the Gujarati middle-class families in Bombay is by the Gujarat Research Society in 1941. Though its conclusions are based on an estimation of only one day's diet, it shows a similar inadequacy of Gujarati diet. These surveys do not mention whether the cooked food left after meals was accounted for or not. Their results are included in table II for comparison.

I thank the secretaries of the messes for helping me in collecting the above data and also Major P. C. Rakshit, I.M.S./A.J.R.O., Principal, B. J. Medical College, Ahmedabad, for kind permission to publish this article.

INCRUSTATIONS IN WATER PIPES AS AFFECTED BY FILAMENTOUS IRON BACTERIA

By S. C. PILLAI
R. RAJAGOPALAN

and

V. SUBRAHMANYAN

Department of Biochemistry, Indian Institute of Science,
Bangalore

INCRUSTATIONS and other biological growths in water mains and distribution pipes cause considerable difficulties in water engineering. The control of such obstructions in the pipes, in most cases, largely depends upon the character and composition of the water and the nature of the pipe material. A few years ago some studies were carried out at Bangalore on the tubercular incrustations in water pipes and the importance of the newly discovered species of *Pseudomonas* occurring in the ferruginous tubercles was indicated (Pillai, 1935, 1938). The observations on this bacillus also lent some support to the view expressed by Ellis (1919) in his monograph on 'iron bacteria' that in considering the affinities of the iron bacteria 'we must not expect to find a group of closely connected bacteria, and it seems very likely that in a few years we shall have representatives of iron bacteria from every one of the known classes of bacteria'.

In regard to filamentous iron bacteria in relation to potable waters, a considerable volume of literature has indeed accumulated, but the available information on the occurrence and distribution of these organisms in Indian waters is comparatively meagre. Nevertheless, some valuable observations have been made at certain waterworks in India, e.g. Madras and Negapatnam.

More recently, the present authors have made some observations on the influence of a species of filamentous iron bacteria on the incrustations in water pipes under certain conditions, and the object of this note is to give a brief account of these observations which mainly relate to the water distribution system at the Mysore Spun Silk Mills, Ltd., Chamnapatna. The water for this works (the daily consumption of water is about 100,000 gallons) is from a bore-well situated practically on the bank of a river which is for the best part of the year dry. The well is about 18 feet deep from the ground level. The water is first pumped into a series of settlement tanks from which it is conducted to the mills over a distance of about half a mile by means of underground cast iron pipes (4 inches diameter).

In the settlement tanks may usually be seen a considerable amount of a reddish-brown material forming small masses of a flocculent character and floating on the water. Examination of this material revealed that it is largely

due to the vigorous growth and activity of a species of filamentous iron bacteria (*Leptothrix oehracea*?), and the material is composed mainly of the cells of this iron bacterium, the ferruginous covering of the bacterial cells and the associated siliceous and other matter. The material when found in comparatively bigger masses and attached to the sides of the settlement tanks, also contained other forms of matter, including the eggs of larvæ of insect fauna such as the 'blood worms'.

The above ferruginous flocculent masses, when freshly formed, present the characteristic colour of the freshly precipitated ferric hydroxide, but if they are allowed to stand without further addition of water or if taken out and kept, they become dark brown or blackish due to decomposition of the associated organic matter. Under the conditions obtaining in the reservoirs and the distribution system into which fresh quantities of water are daily pumped, the iron bacterial masses maintain their colour and character. In the pipes these bacteria attach themselves to the sides and grow and cause gradual deposition of ferruginous matter and thus give rise to incrustations of considerable thickness. With a view to studying the nature and extent of the formation of such deposit in the pipes, the 'tail piece' pipe at the delivery side of the pump in the Pump House at Channapatna was thoroughly cleaned and put back, and the development of incrustations in this pipe was closely watched. In the course of a month the pipe showed inside a more or less uniform coating of ferruginous material of the above-mentioned type to the extent of about $\frac{1}{4}$ -inch thickness all over the surface. The deposit thus formed could easily be removed by hand; when it was allowed to dry and then water was pumped through the pipe, the ferruginous deposit was washed out as 'red water'. Examination of the pipe did not reveal any appreciable corrosion of the pipe material, and it appeared that the incrustation formed had derived its material largely from the water.

A number of samples of the incrustations developed in the pipe system were collected and examined, and the results of analysis of a representative sample of the material are given in table I. It was of some interest to observe that the incrustations taken out from the pipe at the farthest point in the distribution system (at the dead end of the system) were blackish presumably due to stagnation of water there and consequent decomposition of the organic matter in the incrustations.

The bore-well water contains considerable amount of iron (table II) and it would appear that the water is derived from a bed rich in iron. Geological survey has also generally shown that the granite in that area is rich in hæmatite.

With a view to finding out a suitable method of removing or reducing the amount of iron in

TABLE I
Chemical composition of the incrustations in the pipes

Composition	Percentage on moisture-free basis
Loss on ignition (organic matter) ..	6.16
Residue on ignition (mineral matter) ..	93.84
Silica and acid insoluble matter (mostly silica, SiO_2) ..	69.31
Iron (Fe_2O_3)*	15.69
Iron, aluminium, etc. (Fe_2O_3 , Al_2O_3 , etc.)†	23.97
Calcium (Ca)	0.75
Magnesium (Mg)	0.36
Sulphate (SO_4)	1.09

* Determined by the potassium dichromate method, using potassium ferricyanide as the external indicator. The ferric iron was reduced to the ferrous state by means of stannous chloride. The excess of stannous chloride was removed by the addition of a saturated solution of mercuric chloride prior to titration against $\text{K}_2\text{Cr}_2\text{O}_7$.

† Qualitative tests for aluminium, chromium and manganese were carried out. Aluminium and manganese were found to be present; chromium was absent. Manganese and aluminium apparently account for the remaining 8.28 per cent under the iron group.

TABLE II
Results of analysis of the bore-well water

pH value	7.6
	Parts per 100,000
Total solids	26.00

Sulphate (SO_4)	7.92
Nitrite (N)	Nil
Nitrate (N)	Nil

* Al_2O_3 relatively inconsiderable amount.

the water to a minimum and thus controlling the development of the iron bacteria and the ferruginous incrustations in pipes, a number of experiments were carried out by filtering the water through different types of filters (such as

the sand filter, 'leaf filter' and the hand filter press) and inoculating the iron bacteria at different levels of iron in the filtered samples of water. When the water was filtered through sand (which was found to be the best of the filters tried) about 45 per cent of the iron originally present in the water was removed. By this process of sand filtration about 43 per cent of the silica was also removed, and it may be noted from table I that silica forms a very considerable constituent of the ferruginous incrustations. Filtration through the 'leaf filter' resulted in the reduction of about 41 per cent of the iron and about 28 per cent of the silica. The other types of filters examined were not found so satisfactory.

The filtered water samples were then inoculated with the special form of filamentous iron bacteria (just a loopful of the inoculum for about 2½ litres of the water). In all the cases the bacterial growth was actively promoted and the characteristic flocculent ferruginous material was formed in about 24 hours. After this period there was no further perceptible increase in the bacterial mass. In the control series, i.e. in the different water samples which did not receive the bacterial inocula, the characteristic ferruginous material was not formed to any appreciable extent. In the case of the sand filtered water, after treatment with the iron bacteria, a further reduction of about 37 per cent of the iron and about 12 per cent of the silica in the water was observed; the corresponding figures for iron and silica in the case of the 'leaf filtered' water are 33 and 8 respectively.

Further experiments were carried out by adding ferrous ammonium sulphate to distilled water (to the extent of about 10 parts of iron per 100,000 parts of the water) and inoculating the iron bacteria into these solutions (in conical flasks of 2 litres capacity). The effect of blowing air into these solutions was also studied; the aeration was carried out by means of the ordinary suction pump attached to a water tap. These preliminary experiments showed that over 90 per cent of the iron added to the water was removed from the solution at the end of about 6 hours, both under the conditions of artificial aeration of the medium and otherwise. The forced aeration had no appreciable effect. The investigation is under way.

The above observations are of considerable importance in regard to iron-bearing waters and their treatment for various uses.

The authors take this opportunity of thanking the authorities of the Mysore Spun Silk Mills, Ltd., Channapatna, for the facilities afforded in the course of the investigation.

The Treatment of General Paralysis of the Insane (Dementia Paralytica)

By W. LEES TEMPLETON

(Abstracted from the *Medical Press*, Vol. 216, 3rd July, 1946, p. 11)

(1) In the treatment of general paralysis of the insane (dementia paralytica) induction of pyrexia by malaria is the method of choice. A recent review in *B.M.J.*, 18th May, 1946, suggests from figures derived from U.S.A. that artificial fever is much more successful than malaria in securing remissions in severe cases, but a perusal of the original paper shows the number of cases treated was only 37, surely too small a series to warrant any final claim of this sort.

(2) This may be repeated with benefit.

(3) The use of antisyphilitic remedies, particularly of the salvarsan series, in addition to malaria, leads to better recovery rates.

(4) Even acute and advanced cases can make good recoveries.

(5) Mental recovery depends upon the stage of the disease at which treatment is given.

(6) An 'allover' recovery rate of 50 per cent may be expected from malaria combined with drug treatment.

(7) Prophylaxis consists in subjecting to malarial pyrexia all cases of syphilitic infection who are resistant to ordinary antisyphilitic treatment, as judged by the serological findings in blood and c.s.f.

(8) As the action of malarial pyrexia is, it would seem, to kill the spirochæte wherever it may be, it is suggested that all cases of syphilis should have at least one course of such treatment. Only by this means does it seem likely that general paralysis of the insane will be wiped out entirely.

A Study of the Course of the Disease in Leprosy

By DHARMENDRA

and

I. SANTRA

(Abstracted from *Leprosy in India*, Vol. 18, April 1946, p. 43)

The subsequent course of the disease has been studied in 336 cases of leprosy detected in 1936-37, in a rural area in Bengal. Two hundred and forty-eight of these cases are still living in the area, while 88 died or left after having been under observation for five years or over.

Amongst the 268 neural cases, there was definite improvement or complete subsidence in over 40 per cent of the cases; in 30 per cent, the disease remained stationary; and in only 26 per cent, it became worse, including the change to the lepromatous type in only 2.5 per cent of the cases.

Amongst the 68 lepromatous cases, clinical improvement was seen in about one-third, although they did not become bacteriologically negative. In the remaining cases the disease either remained stationary or became worse.

Only about a quarter of the cases have taken treatment. In the neural cases, the improvement seen does not appear to be related to treatment; in many cases there has been improvement without any treatment, while in others, the disease has progressed in spite of the treatment. In the lepromatous cases, however, improvement has been seen more frequently in the treated than in the untreated cases.

Intestinal Toxæmia with Hypertension Gastric Fermentation and Distension

Charkaolin is a highly efficient, gas-absorbing and toxin-adsorbing agent, in which two medicaments with complementary actions are associated. It combines a highly-activated vegetable charcoel and Osmo Kaolin, an exceptionally colloidal form of Kaolin prepared by a special process of electro-osmosis.

The therapeutic applications of Charkaolin include flatulence, diarrhoea, colitis, and dysentery. It has been found useful in some cases of high blood-pressure associated with intestinal toxæmia. Charkaolin has proved highly successful in removing gas from the intestines before intravenous urography and before cholecystography.

CHARKAOLIN

In bottles containing approximately 6 ozs.

ALLEN & HANBURYS LTD • CLIVE BUILDINGS • CALCUTTA

Agent : Ralph Paxton, 12, Lall Bazar, Calcutta.

AS SUPPLIED TO THE GOVERNMENT OF INDIA.

Made in England by T. J. Smith & Nephew, Ltd., Hull.

NOT NERVOUS BUT 'NERVY'

Even in these days there is little evidence of nervousness, but overwork and strain make themselves felt however much their external manifestations be controlled.

Thus the overworked business man may suffer from headaches and insomnia, for the relief of which he needs a sedative that will increase his working capacity.

VEGANIN satisfies this need. It is composed of acetylsalicylic acid, phenacetin and codeine, each in small but sufficient dosage, and has a specific synergistic effect in disorders consequent on over-strain.

VEGANIN is neither toxic or habit-forming. It is not advertised to the public.

ACETARSOL VAGINAL COMPOUND

— BOOTS —

VAGINAL ANTISEPTIC

Acetarsol Vaginal Compound—Boots is a preparation containing acetarsol with boric acid and carbohydrate for local application in the treatment of leucorrhoea associated with *Trichomonas vaginalis*.

Clinical results have shown that Acetarsol Vaginal Compound—Boots is superior to vaginal douches, and the patient is spared much inconvenience on account of the ease with which treatment can be carried out.

Supplied in tablets each containing
4 gr. acetarsol
Tube of 10 tablets

For particulars

CALCUTTA BOMBAY Br. COCHIN

Manufactured by:

BOOTS PURE DRUG CO., LTD. NOTTINGHAM, ENGLAND

The study confirms the prognostic value of the lepromin test.

In the lepromatous type, a few cases had a weak positive reaction, and improvement has been seen more frequently in these cases than in the larger group of lepromin-negative lepromatous cases.

In the neural cases, improvement and subsidence was more frequent in the larger lepromin-positive group than in the smaller lepromin-negative group. Moreover, the change from the neural to the lepromatous type was confined to the lepromin-negative group.

Amongst the neural cases, definite improvement and complete subsidence was much more frequent amongst the group having only patches, than in the group having sensory changes in the extremities, with or without patches.

The average duration of the disease in the neural cases under observation has been 18 years, the shortest period being 9 and the longest 56 years.

The average duration in the lepromatous cases has been 19 years, the shortest being 9 and the longest 36 years.

The average age at death of the neural cases has been 42, and the average duration of the disease at death has been 20 years. In the lepromatous cases, the average age at death and the average duration of the disease at death have been slightly lower, being 38 and 17 years respectively.

The change in type from the neural to the lepromatous has been seen only in about 2.5 per cent cases. The lesions of the neural type most likely to change later into the lepromatous type are the small rather ill-defined flat patches with little or no definite sensory changes, and with a negative lepromin reaction.

Spirochaetal Jaundice (Weil's Disease) Does it Occur in South Africa?

By G. BUCHANAN

(Abstracted from the *South African Medical Journal*, Vol. 20, 14th September, 1946, p. 507)

No evidence of spirochaetal jaundice was demonstrated in over 200 jaundiced patients investigated.

No rats and other rodents examined were found to harbour the causal spirochaete.

The leptospiræ present in local slimy waters produced no ill effects in guinea-pigs.

Survival of Penicillin-Sensitive Organisms in Dried Penicillin

By H. PROOM

(Abstracted from the *Lancet*, ii, 6th July, 1946, p. 11)

DRIED pathogenic penicillin-sensitive organisms may remain viable for a considerable period—at least 10 weeks—in contact with commercial dried penicillin. This mixture when dissolved and injected into animals may cause infection.

In practice the risk of infection from contaminated dried penicillin is small, but it is sufficient to make it advisable to test the sterility of dried penicillin before use.

Changes in the Concentrations of Carotene and of Vitamin A in the Blood of Sheep Grazing on Natural Pastures in South Australia

By A. W. PEIRCE

(Abstracted from the *Australian Journal of Experimental Biology and Medical Science*, Vol. 24, September 1946, p. 231)

In Merino sheep which grazed on natural pasture the concentration of vitamin A in the blood was found to lie between 25 γ and 35 γ per 100 ml. plasma. The concentration was not affected by changes in the intake

of carotene from 1 mg., while grazing on dry pasture in the autumn, to 2 gm. per day while grazing on green pasture in the spring. There was, however, a slight but significant increase in the concentration of vitamin A in the blood with age. Carotene was present in the blood in measurable amounts only when the sheep were grazing on green pasture. The amounts at such times, however, were only 5 to 15 per 100 ml. plasma, or 10 to 20 per cent of the total vitamin A potency of the blood.

In an area where perennial bush (*Kochia scdifolia*) formed the major constituent of the diet, the concentration of vitamin A in the blood was found to lie within the normal limits except at the end of a period of two years in which the rainfall was below normal. At this time the concentration had fallen to about two-thirds of the normal value.

In all the sheep which were examined the reserves of vitamin A in the liver were adequate; they ranged from 230 γ to 810 γ per gm. liver. Carotene was present to the extent of only 2 γ to 5 γ per gm. liver.

Benadryl

(From the *New Orleans Medical and Surgical Journal*, Vol. 98, May 1946, p. 511)

AND now another new drug, this time one to be used in the symptomatic relief of urticaria, hay fever and vasomotor rhinitis.

Benadryl, a new anti-histamine substance, promises to relieve the oedema produced by the histamine or histamine-like substances in these conditions. It decreases the cutaneous vasodilatation and has an antispasmodic effect on smooth muscle. Chemically the drug is beta dimethylaminoethyl benzhydryl ether hydrochloride.

In a recent symposium by members of the Mayo Clinic Staff, the results in the treatment of urticaria, hay fever and asthma, vasomotor rhinitis and serum reactions are enumerated and discussed. The authors found that the symptoms of urticaria were relieved in most cases, often as soon as one hour after the first dose, and in a few cases the attack of urticaria was terminated. Relief was also obtained in patients with angioneurotic oedema. The dosage varied from 50 to 100 mg. daily by mouth.

In hay fever patients almost complete relief was often obtained after two or three doses of 50 mg. of benadryl by mouth daily. After the first dose symptoms were relieved within one hour and the effect lasted from five to eight hours. In asthma, the drug was less effective, only a few patients getting partial relief.

In children the symptoms of these disturbances and serum reactions were relieved. Approximately 2 mg. of benadryl daily per pound of body-weight seemed to be adequate.

The drug may be given intravenously, intramuscularly or orally. It is moderately irritating when given intramuscularly. Side effects are greater with oral than parenteral administration and include drowsiness, dizziness, dry mouth and nervousness. All are transient and mild. Nausea and vomiting may require discontinuance of therapy. Since the drug decreases gastric acidity in some cases, it may offer a new approach to the control of gastric acidity. Drowsiness, not undesirable at bedtime, may be combated during the day with caffeine or benzedrine, and nervousness is not marked if the daily dosage is kept small.

The new drug, now available, opens vistas of relief for those sufferers of these annoying conditions.

Evaluation of Anthallan Treatment of Neurodermatitis Disseminata and Urticaria

By L. SCHWARZSCHILD

(Abstracted from the *New York State Journal of Medicine*, Vol. 46, 15th July, 1946, p. 1563)

THE therapeutic usefulness and safety of anthallan was studied in 35 cases of neurodermatitis disseminata,

41 cases of urticaria, and 8 cases of papular urticaria. None of these cases had shown any improvement in preliminary periods of observation under our supervision, nor under therapy which included many types of the usual specific or non-specific, local or systemic measures, or in subsequent periods when placebos were given. A significant beneficial influence was observed in about 80 per cent of the 84 cases treated with anthallan, this improvement varying between 50 and 100 per cent as evaluated by an objective scale herein outlined. Thirty-one of 35 cases of neurodermatitis disseminata, 36 of 41 chronic urticaria cases and all 8 cases of papular urticaria obtained an objectively recorded and verified benefit from anthallan such as they had not obtained from any other treatment given before.

In a large majority of the patients the beneficial therapeutic result observed at the end of anthallan treatment persisted. Partial relapses were few and only 2 cases evidenced complete relapse. These responded well to a second course of anthallan therapy.

Except for one case of transient and promptly reversible diarrhoea, clinical examination and laboratory studies of various kinds revealed no indications of toxicity produced by treatment with anthallan.

The mechanism by which anthallan exerts its activity is still obscure, nor are the entire scope and limitations of its usefulness clear. However, it is apparent from the results of this study that with the dose averaging 8 capsules daily for seven to seventy days, anthallan is a valuable and safe therapeutic agent for the treatment of those cases of neurodermatitis disseminata and chronic urticaria, which are not amenable to other forms of therapy.

Asthma and Urticaria following a Bee Sting

By H. REED

(From the *East African Medical Journal*, Vol. 23,
August 1946, p. 245)

THE patient, a European, aged 31 years, in whose house I happened to be staying, was going out of the back door at about 6-30 one evening when he was stung on the left ear by a bee. He thinks it was larger than the ordinary honey bee but was unable to see exactly what type it was as he hastily brushed it off and it flew haltingly away. The pain was so severe that he rubbed the ear between finger and thumb and in doing so dislodged the sting which had been left behind.

Within two or three minutes his face became flushed, his head began to throb and he felt so weak that he was glad to flop into an easy chair. Quite suddenly the nasal mucosa swelled so that he was compelled to breathe through his mouth, just as if someone had abruptly grasped his nose. A minute or so later he began to wheeze and had to breathe deeper and more forcefully. An attack of asthma immediately developed.

Half c.c. of adrenaline quickly gave relief, and he was able to cough up a little mucus and blow some out of his nose, but the respite was short-lived. Very soon unpleasant pink blotches began to make their appearance on the skin of his arms and within a few minutes his whole body was decorated with urticarial wheals.

Ten minims of adrenaline were then injected at rate of one minim per minute and this treatment caused a marked improvement in his breathing and in the state of the rash but he felt so shaky and chilly that he decided to go to bed, two ¼-grain tablets of ephedrine being given to prevent a return of the symptoms. The foregoing events all took place within the space of about 30 minutes but despite the ephedrine the symptoms began to return slowly.

At about 8 p.m., he was given a further injection of adrenaline 5 minims and two more ¼ grain tablets of ephedrine. At 9-30 p.m., however, yet another injection of 5 minims of adrenaline was required.

Luminal 3 grains were then given and the patient soon went to sleep and slept until early morning.

It was interesting to note that whilst the adrenaline and ephedrine controlled the asthma and urticarial wheals they appeared to have no effect upon an erythema which appeared all over the body. It was especially marked in the flexures and closely resembled a scarlatinal rash.

The next morning the patient felt very weak and vomited his morning tea as soon as he drank it. The nausea and vomiting persisted during the morning and since the patient had been having frequent attacks of malaria, a blood slide was taken and on microscopic examination, a few subtertian malaria parasites were seen. A quinine injection 9 grains was given at once and repeated in the evening.

The erythematous rash and the accompanying irritation gradually faded during the following 48 hours but the malaria did not clear up for several days.

The patient had been stung a few times by bees in England and in March 1944, 20 months previously, whilst on safari in Lake Province, he had been stung on the scalp by four or five bees but on no occasion was there any reaction beyond the local pain and swelling and some slight enlargement and tenderness of the regional lymph glands. He himself had never before shown any hypersensitivity reaction. The patient's father, however, as a young man suffered from urticaria which was caused by eating potatoes. Later on he developed 'hay fever' and finally asthma. His father's brother had occasional slight attacks of asthma and his sister had 'hay fever'.

An Epidemic of a Severe Pneumonitis in the Bayou Region of Louisiana

By G. L. FITE *et al.*

(Abstracted from *Public Health Reports*, Vol. 61,
26th July, 1946, p. 1100)

RELATION OF THE LESIONS PRODUCED IN ANIMALS BY LOUISIANA PNEUMONITIS VIRUS AND THE RICKETTSIAE

THE many studies of the rickettsial diseases, especially typhus and Rocky Mountain spotted fever, in laboratory animals, Mooser, Hach, and Lillie and Dyer have shown that in these diseases the viscera of infected guinea-pigs are not involved to the same degree as are the viscera of guinea-pigs infected with Louisiana pneumonitis virus or the viruses of psittacosis and meningopneumonitis. Occasional foci are found in the brains of certain guinea-pigs inoculated intraperitoneally with Louisiana pneumonitis virus and these bear a close similarity, or even identity, to those seen in guinea-pigs similarly infected with typhus or spotted fever virus. Although the lesions are less extensive and less well developed, their relation to blood vessels appears to be the same as that of the lesions noted in the rickettsial diseases. The foci in the testes of guinea-pigs infected with Louisiana pneumonitis virus are also similar to lesions seen in the testes and scrotum of guinea-pigs infected with rickettsiae of typhus fever. The presence of infiltrating mononuclear cells is reminiscent of typhus fever infections. The tendency of Louisiana pneumonitis virus and the viruses of psittacosis and meningopneumonitis to produce fibrin thrombi in capillaries is far greater than that of typhus fever rickettsiae.

SUMMARY AND CONCLUSIONS

The virus of Louisiana pneumonitis produces extensive lesions in mice, guinea-pigs, and cotton rats, following intraperitoneal inoculation. In albino rats and hamsters, lesions are produced by large doses of the infecting agent but the virus is infrequently lethal for these animals. Rice rats, muskrats, ferrets, deer mice, nutria, and rhesus monkeys are not susceptible to infection with this virus. The variation in the quality of the lesions produced in mice, guinea-pigs, and cotton rats by the Louisiana pneumonitis virus

must be considered one of its distinctive features. In mice infected intraperitoneally or intracerebrally the lesions produced are probably indistinguishable from those caused by the viruses of psittacosis and meningopneumonitis. In mice infected intranasally with Louisiana pneumonitis virus the resulting pneumonic process shows material differences from the lesions in mice similarly inoculated with the other agents. There is no bronchial involvement and no tendency toward interstitial spread of infection in the lungs of mice infected with the agent under study.

The infection in guinea-pigs is characterized by extensive fibrinous thrombosis of capillaries and sinuses of the liver and spleen, with comparatively less cellular reaction than observed in the mouse.

An extensive plastic fibrinous peritonitis constitutes the chief alteration in cotton rats. Comparatively trivial changes occur in the organs.

Animals intracerebrally inoculated show a dry meningitis with slight extension of the process into the superficial brain tissues along the blood vessels. Mice and guinea-pigs infected intraperitoneally occasionally may show lesions in the brain similar to those occurring in guinea-pigs infected with the rickettsia of typhus fever or spotted fever.

Experience with BCG Vaccine in the Control of Tuberculosis among North American Indians

By J. D. ARONSON

and

C. E. PALMER

(Abstracted from *Public Health Reports*, Vol. 61, 7th June, 1946, p. 802)

THE present paper gives the results of a study, begun in December 1935, on the effect of BCG vaccination on the incidence of tuberculosis among American Indians. The study group consisted of 3,007 persons, ages 1 to 20 years, who were selected from a larger group on the basis of a negative tuberculin reaction. BCG vaccine was given intracutaneously to 1,550 with 1,457 serving as controls. These persons were followed for 6 years with annual tuberculin tests and chest x-ray examinations.

Tests of the vaccinated and control groups as to age, amount of exposure to tuberculosis, and completeness of follow-up indicate that the two groups are comparable in these respects.

Results from the analysis of the records show that BCG vaccination is associated with marked protection against the development of tuberculosis as measured by mortality and morbidity experience of the two groups.

During the 6-year period, 60 deaths from all causes occurred among the 1,457 persons in the control group compared with 34 among 1,550 vaccinated. In terms of deaths per 1,000 person-years, the death rates were 7.2 and 3.8, respectively. There were 28 deaths assigned to tuberculosis among the controls as compared with only 4 such deaths among the BCG group.

Comparison of cases, as determined mainly from radiological evidence, supplemented by data from tuberculin tests, revealed similar wide differences between the two groups. Including those that died from tuberculosis, 48 cases were classified as having extrapulmonary tuberculosis or advanced pulmonary lesions among the controls while only 9 such cases were found among the vaccinated. There were 20 cases showing x-ray evidence of minimal lesions among the controls and 8 among the vaccinated. The corresponding figures for cases showing enlarged hilar glands were 99 and 19, respectively, and for pleural effusion 18 and 4, respectively.

The comparison for total incidence, cases of all types and deaths, is that of 185 among the controls and

40 in the vaccinated. In terms of cases per 1,000 person-years, the rates were 24.3 and 4.7, respectively.

There is no evidence from the analysis that a diminution of immunity occurred with the passage of time after vaccination. On the contrary, indications were that the protection may be greater in the later than in the earlier years after vaccination.

The total incidence of cases among the controls was nearly constant for all age groups, while among the vaccinated there was a marked decrease in incidence with advancing age. The evidence is suggestive, although not conclusive, that BCG vaccination may be more effective in the older than the younger children.

Some variation in the effectiveness of the different lots of vaccine was noted. Lots 8, 9, and 10 appeared to afford much less protection than the others used.

A Dressing for Burns and Extensive Abrasions

By G. S. KING

(From the *New York State Journal of Medicine*, Vol. 46, 15th July, 1946, p. 1567)

THROUGHOUT the past two decades the treatment of extensive burns and abrasions has undergone most decided changes. First, in the recognition that the injury, *per se*, is not so much the causative factor in the patient's condition, after initial shock, as the accompanying local and general sepsis which occurs after the injury.

Immediate treatment of the initial injury to combat subsequent sepsis and, perhaps more important the immediate initiation of medical treatment to combat systemic poisoning is now the accepted procedure. The administration of plasma, blood transfusions, intravenous feedings with glucose or amigen solution, the sulpha drugs, penicillin, all pay their life-saving rôles. Local application of remedial substances, ointments, solutions, the compresses, etc., has been the standard procedure for centuries, the only difference being the type of drug or solution used and, as knowledge of the technique of preventing and combating surface infection has grown, these medications have been changed to conform to that knowledge, although many of the older and time-proved remedies are still in ethical and beneficial use.

The method of application of these local medications is the main factor in the treatment of burns or abrasions that has not been very radically changed or modernized. Medications are still applied to the denuded surfaces of burns or abrasions on gauze. Occasionally, paraffined mesh is used but gauze is the general medium of application.

No matter how thoroughly gauze is soaked in aqueous, oily or greasy media, it has a certain amount of capillary attraction and has a tendency to adhere and actually grow fast to a denuded area. Changing dressings, especially removal of a soiled dressing, is usually the most painful part of the treatment of a severe burn or abrasion.

A new form of dressing for burns and abrasions, especially those of the extensive variety, in the form of a perforated film of very thin cellophane has been described. The E. I. du Pont de Nemours Company of Wilmington, Delaware, manufactures a thin cellophane film, perforated with 1/32-inch holes on a 3/32-inch centre, which is ideal for the type of surgical dressing suggested. This cellophane film may be sterilized in an autoclave or by immersing in alcohol and drying. As a surgical dressing it is ideal if used in the following manner:

To the upper surface of a strip of perforated cellophane apply a generous coating of medication—sulpha, penicillin, or any ointment of choice. Apply the medicated film face down; that is, the perforated cellophane surface directly on the denuded area, the ointment being on top of the film. Cover the medicated side with a strip of non-perforated cellophane film, thus forming a sealed container of ointment over the wound. Using a series of perforated medicated film strips, covered with non-perforated film strips, the

wound is completely covered with an air-tight, germ-proof housing over any desired area.

Simple bandages hold the dressing in place. If desired, compression bandages may be applied. Any excess of the medication as it melts and seeps over the wounded surface, exudate from the wound, or serum, gravitates downwards to absorbent material placed at the lowest margin of the wound, or beneath the injured member. This excess exudate, when collected on the absorbent material, may be readily changed without disturbing the original dressing. This form of dressing allows frequent dressing of the wound. It is absolutely non-adherent and may be removed without pain or discomfort to the patient. This form of dressing requires less frequent changes than gauze dressing. It is less expensive as it requires very much less medication than the same medication applied on gauze. The cellophane film is inexpensive. This dressing can be applied in much less time than gauze dressing and it is almost ideal for skin graft. Being transparent, the wound may be inspected without removal of the dressing.

At present, the perforated cellophane film as well as the pliable non-perforated film are not readily obtainable, but should soon be marketed by surgical houses, if there is any demand for such film by the medical and surgical profession. In a previous article, the use of envelopes of cellophane with the bottom side perforated was suggested. Since the publication of the aforementioned articles, the perforated film was found and this newer and simpler form of application is recommended.

Angina Pectoris

(Abstracted from the *Medical Journal of Australia*, Vol. 1, 4th May, 1946, p. 632)

PICKERING AND SANDERSON, in returning to the old subject of tobacco and its bearing on the production of angina, are not convinced by many of the case records in the literature. Though it is generally believed that tobacco can cause disturbances of rhythm and can be responsible for attacks of pain, they feel that the pattern of anginal attacks described as occurring in relation to smoking often does not resemble the true angina of effort.

Nevertheless, the real point is that to prevent anginal attacks the heart rate must be kept down, and even if tobacco seems insecurely established as a contributory cause, reasonable clinical evidence is warrant for its curtailment. It might be interesting to raise the question of the possibility of tobacco enhancing the response of the cardiac nerve endings to the hypothetical pain substance but this would be difficult to answer. Efforts of various kinds have been made to interrupt the neural path of pain. Occasional success has rewarded the surgical division of the path in the upper sympathetic chain, and more recently an attempt has been made to arrest pain at the thalamic level.

A. S. Freedberg and J. E. F. Riseman record some success from the use of cobra venom. This powerful substance has been found to act as a sedative on the central thalamic mechanism and has been used to relieve the pain of inoperable cancer.

They now present a study of twelve patients who have been treated in this way.

Cobra venom was injected into the deltoid muscle in doses of ten to twenty mouse units, in a volume of one to two millilitres, daily for three to seven days till a therapeutic effect was obtained. An increase in exercise tolerance was obtained varying from 25 per cent to 75 per cent, the degree of improvement not running parallel to the previously observed response to vasodilators. Indeed several patients who had gained no relief from nitroglycerin were benefited by the venom. The electrocardiographic findings after exercise were not altered, even though pain was relieved. Results were only temporary in most cases, and a biweekly maintenance dose was necessary, though in one instance even this did not prevent a return of pain as before.

In *angina pectoris* there are three possible points of attack; to limit the causal exertion and thus to keep down the heart rate, to relieve coronary ischaemia, and to curb the nervous mechanism that registers pain.

This question has often been raised: If we succeed in preventing anginal pain, do we expose the patients to the risk of damaging his heart by rash overwork? Experience has so far returned a favourable reply—with discretion in the matter of exertion the heart is not in greater peril because its threshold of pain more nearly approaches the normal.

Penicillin Lozenges

By R. C. PARNABY

(From the *Pharmaceutical Journal*, Vol. 156, 8th June, 1946, p. 371)

PROFESSOR BERRY suggests that patients using penicillin lozenges should be instructed to suck, not to chew the lozenges. My advice has always been that they should be retained in the buccal cavity, for by so doing each lozenge of the compressed type persists for almost two hours. As the usual direction has been 'one lozenge two-hourly' it can be seen that the saliva is bacteriostatic almost continuously. A specimen of saliva taken after 30 minutes of retention of a lozenge in the buccal cavity definitely inhibited the growth of *Staphylococcus aureus*, Oxford strain. Thus a very real economy in the consumption of the lozenges can be effected without sacrificing their efficiency and it would be in the interest of the patient.

Reviews

AN INTRODUCTION TO BACTERIOLOGICAL CHEMISTRY.—By C. G. Anderson, Ph.D. (Birm.), Dip.Bact. (Lond.). Second Edition. 1946. E. and S. Livingstone Limited, Edinburgh. Pp. x plus 500. Price, 20s.

ON the biochemistry of micro-organisms this handy volume supplies, in a small compass, information which is spread out in many and larger books. The chapter on the isolation and identification of metabolic products though only an introduction to the subject is remarkably informative. Antibiotics, chemotherapy and immunology have been included as associated subjects.

Direct communication has been established with the election in therapeutics (p. 141). Antibodies have been given size and shape, and the peptide chains at their ends visualized (p. 422).

Possibly some details of formulae could be deleted without detriment to the bacteriologist. The space so created could be filled by more matter under Alcoholic fermentation and Industrial fermentation. Apparently useful details of preparing alcoholic beverages remain the secret of the industrialists.

Of the resistance said to be developed by bacteria to penicillin, because of small dosage (p. 176), now there is no evidence. Unlike what happens in the case of sulpha drugs, it can be overcome by a bigger dose.

On page 434, para 2, line 7, 'activation' should be 'inactivation'.

The paper, printing and binding are good. The price could have been a trifle lower and more in keeping with that of books of the same size on bacteriology and chemistry.

A very useful book for bacteriologists and immunologists. S. D. S. G.

THE HUMAN APPROACH: A BOOK FOR MEDICAL STUDENTS.—By Henry Yellowlees, O.B.E., M.D. (Glas.), F.R.F.P.S. (Glas.), F.R.C.P. (Edn.), F.R.C.P. (Lond.), D.P.M. (Lond.). 1946. J. and A. Churchill Limited, London. Pp. vii plus 189. Price, 10s. 6d.

THIS book includes amongst other useful hints on the contact between the patient and the physician a diplomatic approach to the jury in the matter of criminal responsibility on which medicine and law do

not see eye to eye. The psychiatrist, according to the author, should manage to convey to the jury what the judge is bound to disagree with, concessions which go beyond the McNaughten rules. The move usually succeeds. Even when it fails, the prisoner, after conviction, receives the benefit of another examination by psychiatrists.

The other hints are undoubtedly true and practical. But whether a student (for whom the book is stated to be written) will appreciate them is open to question by mature medical men with experience of teaching.

Psychological items which have entered parlance in medical circles during the last two decades (unconscious mind, projection, phantasy, herd, anxiety, inferiority, rehabilitation, etc., etc.) are explained concisely. At times Alice in Wonderland and a crack golfer combine forces to drive a point home.

With the 'utterly fallacious distinction between bodily and mental symptoms' and the inadvisability of telling a syphilophobic who is not suffering from syphilis that there is nothing the matter with him, one may not agree.

There is no index but the readability of this small book and a table of contents make up for this loss.

The paper, printing and binding are good. No printer's errors attract attention.

S. D. S. G.

MEDICAL ASPECTS OF GROWING OLD.—By A. T. Todd, M.B. (Edin.), M.R.C.P. (Lond.). 1946. John Wright and Sons Ltd., Bristol. Pp. 164 with 13 figures. Price, 15s.

In this unique book the author expresses his personal opinions on matters of comfort, health, life and death of maturing and mature people. There is no lack of confidence in the expression. Here are a few instances: (1) Blood pressure above the normal, after a certain age, need not worry anyone. It varies with the build as is shown by the thigh recording a higher reading than the arm. One agrees. (2) Allergy is not specific essentially. A hidden focus causes the primary trouble. Later, all sorts of antigens begin to react. One may agree. (3) Milk proteins, specially the lactalbumen, are poisonous unless denatured by churning. One may not agree: they may not agree with some subjects, but do agree with the majority. (4) Adapt your foot to the shoe. One does not agree. Even a little study in the classification of the foot (depending on the arch and relative length of the great and the next toe) enables one to choose the shape. When possible the shoes should be made to measure. When not possible they should be modified according to the measure. The makers will wrap canvas round a part of one foot of a pair of the last to make the smaller side bigger: one foot is always bigger than the other. Shoes have been made by this device, by firms of repute, at very little extra cost.

Chapters on exercise, genito-urinary troubles, and skin and hair are excellent, and do not lend themselves to controversy.

The book when not informative is provocative of thought. Is well worth reading.

The paper, printing and binding are excellent. A minor printing error occurs on page 143: in 3rd para, 1st line, after ':' there should be '(1)'.

S. D. S. G.

INTRODUCTION TO CLINICAL NEUROLOGY.—By Gordon Holmes, M.D., F.R.S. 1946. E. and S. Livingstone Limited, Edinburgh. Pp. vii plus 183. Illustrated. Price, 12s. 6d.; postage, 6d. (home)

The special feature of this little book is the lucid exposition of the correlation between neuro-physiology and clinical neurology.

While all essential details are presented in an easily assimilable logical sequence, those of the autonomous nervous system and of the disorders of speech are particularly arresting.

The practitioner will find the book pleasantly reminiscent and the student useful.

S. D. S. G.

CARDIOVASCULAR DISEASE IN GENERAL PRACTICE.—By Terence East, M.A., D.M. (Oxon.), F.R.C.P. (Lond.). Second Edition. 1946. H. K. Lewis and Company, Limited, London. Pp. x plus 188, with 40 illustrations. Price, 12s. 6d.

As most patients die ultimately from failure of the heart and most of them while so dying are under the treatment of general practitioners, it is meet and proper that the recent advances in cardiovascular diseases should be made plain to the general practitioner. This is done in this little book by a cardiologist. He does it thoroughly and without the aid of the electrocardiogram (excepting the merest mention of T on page 16).

Most elementary matter is included for here the most serious mistakes are likely to be made.

Among other elucidations the recognition by simple signs of the extra systole, heart block, palpitation, effort syndrome, imagined heart disease and heart attack is made easy.

The average medical man cannot fail to find the book both interesting and instructive.

The paper, printing and binding are excellent. No printer's errors attract attention.

S. D. S. G.

EYE SURGERY.—By H. B. Stallard, M.B.E., M.D. (Cantab.), F.R.C.S. (Eng.). 1946. John Wright and Sons Ltd., Bristol. Pp. xi plus 444, with 338 illustrations. Price, 50s.

ANYONE familiar with the author's work and publications will expect to find clarity of expression and minute attention to detail. They will not be disappointed in this book. As Sir John Parsons points out in a foreword, the author does not attempt to enumerate a large number of alternative methods of performing various operations but rather to record the methods adopted by an experienced surgeon. Thus with each operation recorded one obtains a wealth of information as to exact details of technique and surgical minutiae—information that is often lacking in those works which for the most part describe the techniques used by others. Particularly valuable are the chapters on The Eyelids and Reconstructive (Plastic) Surgery and Traumatic Surgery, civil and military. Here is recorded much of the author's experience as a Military Surgeon during the last war. While some surgeons may prefer their own technique for a particular operation in some cases, all will read the book with the greatest pleasure and profit. There are 338 illustrations many of which have been beautifully drawn by the author himself. The book should be read by all ophthalmic surgeons.

E. J. S.

SQUINT AND CONVERGENCE: A STUDY IN DIOPHTHALMOLOGY.—By N. A. Stutterheim, M.D. (Rand). 1946. H. K. Lewis and Company, Limited, London. Pp. vii plus 95, with 26 Graphs and 15 Diagrams. Price, 15s.

THE author states that many years ago he 'operated and corrected ametropias, as many others did, with of course the usual unsatisfactory results'. As the result of the little success that he obtained with the more orthodox types of operation, he started treating squint case by means of a battery of prisms of varying degrees—a method he terms di-ophtalmology. The treatment takes about one year of daily attendance to complete during which most patients must wear an occluder over one eye. The author suggests that during this year's treatment the patients 'should

preferably be taken out of their home surroundings, which often form a drawback to the treatment' and 'should be placed together in special hostels attended by school nurses'. In spite of this prism treatment, of the twenty-six cases described, twenty-one eventually required surgical intervention. The author does not appear to care for the word 'operation' and prefers to use the term 'surgical adjustment' for the procedure he uses. This consists of an operation for the adjustment of Tenon's capsule which is shortened by a technique originally described by Von Wecker in 1888. The book could be improved by a more lengthy and detailed description of the use of the battery of prisms and some pictures showing the stages in the operation. The book will be of interest to ophthalmologists.

E. J. S.

AMERICAN POCKET MEDICAL DICTIONARY.—

Edited by W. A. Newman Dorland, A.M., M.D. Eighteenth Edition. Published by W. B. Saunders Company, Philadelphia and London. Pp. 1081. Price—Plain edition 10s. With thumb index 12s. 6d.

MANY practitioners are no doubt familiar with this book which gives the pronunciations and concise definition of medical terms arranged alphabetically and with many tables which are convenient for quick reference. First published 50 years ago, it has gone through eighteen editions, so it needs no introduction. In this edition the book includes many new terms that have appeared in the literature during the last four years, covering almost every branch of medicine. Few of us can turn over its pages without getting a little wiser.

Any Questions

PFEIFFERELLA WHITMORI

SIR,—In the September 1946 issue of the *I.M.G.* on page 368, 2nd column, under the 'Tenth Clinical Meeting of the Calcutta School of Tropical Medicine', para (2) *Bacillus whitmori* is described as a Gram-negative organism.

In Napier's *Principles and Practice of Tropical Medicine*, 1943, on page 365, the same organism is described as Gram-positive.

Will you please tell us which of these statements is correct?

Also, perhaps you can tell us when part II of Napier's *Principles and Practice of Tropical Medicine* can be had. The recognized booksellers in India are not able to help.

Yours, etc.,

'ARUNDEL COTTAGE', B. J. BOUCHÉ, M.R.C.S., L.R.C.P.,
MUSSOORIE. MAJOR, I.M.D. (Retd.)

(On page 492 of 'Topley and Wilson's *Principles of Bacteriology and Immunity*', 3rd edition, revised by G. S. Wilson and A. A. Miles, 1946, the morphology of *Pfeifferella whitmori* is described as follows:—

'Small, slender rods, 1-2 μ long and 0.4-0.5 μ broad; sides parallel, ends rounded, axis straight; arranged singly, in pairs end-to-end, or sometimes in long parallel bundles, the bacilli being embedded in an interstitial substance. Variations occur in depth of staining; bipolar staining common, especially in films from infected tissues. Motile; Gram-negative; acid-fast granules have been described in freshly isolated strains (Finlayson, 1944). The short, oval, bipolar-stained rods are characteristic of the rough form; the longer, narrower rods, arranged in palisades with irregular staining and shadow forms, are characteristic of the smooth variant.'

Part II of Dr. Napier's '*Principles and Practice of Tropical Medicine*' is now in the final stages of printing and is expected to be out soon.—EDITOR, *I.M.G.*

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL E. G. MONTGOMERY is appointed Principal of the Medical College for Licentiates, Calcutta, and Superintendent of the attached Hospital with effect from the 28th October, 1946.

Major F. H. A. L. Davidson, Civil Surgeon, Dacca, is appointed to be Civil Surgeon, Darjeeling, vice Major J. Brebner.

The undermentioned officers of the I.M.S. (E.C.) revert from the I.A.M.C. and are seconded for service in the Royal Indian Air Force:—

Captain S. R. Kidiyoor. Dated 30th August, 1946.

Captain B. K. Basu. Dated 5th September, 1946.

Captain G. C. Sen Gupta. Dated 11th September, 1946.

The undermentioned officers of the I.M.S. (E.C.) are granted Emergency Commissions:—

ROYAL INDIAN AIR FORCE—MEDICAL BRANCH

To be War Substantive Flight-Lieutenants

Captain S. K. Muhury. Dated 21st August, 1946.

Captain B. K. Basu. Dated 5th September, 1946.

Captain K. S. Rao. Dated 6th September, 1946.

Captain G. C. Sen Gupta. Dated 11th September, 1946.

LEAVE

Lieutenant-Colonel J. C. Drummond, Civil Surgeon, Chittagong, is granted leave for 6 months, with effect from the 14th November, 1946.

Major J. Brebner, Civil Surgeon, Darjeeling, is granted leave for 8 months, with effect from the 28th December, 1946, or from the date of relief.

PROMOTIONS

Lieutenant-Colonel W. O. Walker, I.M.S. (retd.), on reversion to retirement, is granted the honorary rank of Colonel, 20th February, 1945.

INDIAN MEDICAL SERVICE

SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

(WOMEN'S BRANCH)

Lieutenant to be Captain

Miss N. K. Sumana. Dated 5th January, 1946.

RELINQUISHMENTS

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Colonel :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Colonel Mohammad Ziaullah. Dated 10th July, 1946.

The undermentioned officers are permitted to relinquish their commission on release from army service and are granted the honorary rank of Lieutenant-Colonel :—

Ty. Lieutenant-Colonel Velacheri Kuppuswamy Sundaram. Dated 14th October, 1946.

Ty. Lieutenant-Colonel R. A. Davar. Dated 8th November, 1946.

Ty. Lieutenant-Colonel Prasanta Kumar Chatterjee. Dated 8th November, 1946.

Ty. Lieutenant-Colonel V. R. Thayumanaswami. Dated 10th December, 1945.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Ty. Major R. Subramanian. Dated 13th March, 1946.

Ty. Major Ranjit Singh Garewal. Dated 19th August, 1946.

Ty. Major A. Krishnan. Dated 4th September, 1946.

Ty. Major G. S. Guha. Dated 13th September, 1946.

Ty. Major S. C. Driver. Dated 26th September, 1946.

Major Nazir Ahmad Barlas. Dated 30th September, 1946.

Major Billa Narayana Rao. Dated 30th September, 1946.

Major V. Hariharan. Dated 2nd October, 1946.

Major P. J. Engineer. Dated 6th October, 1946.

Ty. Major Thurnthel Chandu John. Dated 27th October, 1946.

Major H. N. Dastur. Dated 4th November, 1946.

Major J. L. G. Pinto. Dated 4th November, 1946.

Major P. F. D'Souza. Dated 15th November, 1946.

Ty. Major Anil Kumar Das. Dated 25th November, 1946.

(WOMEN'S BRANCH)

Ty. Major (Mrs.) C. L. Mary Drummond (née Newman). Dated 5th November, 1946.

Captain P. S. Bhargava, Assistant to Medical Adviser (Pensions), Defence Department (Pensions Branch),

relinquished the appointment, 23rd November, 1946 (afternoon).

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

- Captain N. P. Devadason. Dated 29th April, 1946.
 Captain C. F. Paice. Dated 1st May, 1946.
 Captain Fakir Chandra Mukerjee. Dated 13th May, 1946.
 Captain S. V. Dalvi. Dated 23rd June, 1946.
 Captain Karamcheti Suryanarayana. Dated 17th July, 1946.
 Captain J. V. Nazareth. Dated 30th August, 1946.
 Captain Namuddin Ahmed. Dated 23rd September, 1946.
 Captain Jyotish Chandra Ghosh. Dated 26th September, 1946.
 Captain Satyendra Ramchandra Turkhud. Dated 6th October, 1946.
 Captain Bala Sahay. Dated 12th October, 1946.
 Captain M. R. Subha Rao. Dated 15th October, 1946.
 Captain Y. R. Shetty. Dated 16th October, 1946.
 Captain B. P. Sinha. Dated 27th October, 1946.
 Captain M. S. Khan. Dated 29th October, 1946.
 Captain Gangesh Kumar Roy. Dated 2nd November, 1946.
 Captain Siba Prasad Mitra. Dated 3rd November, 1946.
 Captain M. A. R. Chaudhari. Dated 11th November, 1946.
 Captain C. D. Iyengar. Dated 17th November, 1946.

INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)
(WOMEN'S BRANCH)

- Captain Divakar Shantaram Patkar. Dated 23rd June, 1946.
 Captain P. Subrahmanyam. Dated 4th July, 1946.
 Captain Fida Mohd. Khan. Dated 15th July, 1946.
 Captain (Mrs.) J. A. Karim. Dated 19th July, 1946.
 Captain (Miss) Sarah Abraham Shellim. Dated 29th July, 1946.
 Captain S. S. Godbole. Dated 24th August, 1946.
 Captain (Miss) Janaki Bair Vidur Raj. Dated 6th September, 1946.
 Captain Calambakkam Muthukrishnan. Dated 21st September, 1946.
 Captain Sudhindra Nath Ray. Dated 26th September, 1946.
 Captain Kartar Singh Jolly. Dated 26th September, 1946.
 Captain Ramendra Nath Dutta. Dated 30th September, 1946.
 Captain Saradindu Mukerjee. Dated 14th October, 1946.
 Captain C. F. Varied. Dated 17th October, 1946.
 Captain (Mrs.) Rose Swamikan. Dated 18th October, 1946.
 Captain Krishna Kumar Bose. Dated 30th October, 1946.
 Captain M. Rahimulla. Dated 31st October, 1946.
 Captain Michael Colaco. Dated 1st November, 1946.
 Captain Lekshumana Rajagopala Marthandam. Dated 4th November, 1946.
 Captain G. S. Ahmed. Dated 5th November, 1946.
 Captain (Mrs.) G. Barretto (née Neri). Dated 10th November, 1946.
 Captain B. Raghavan. Dated 14th November, 1946.
 Captain Vankatchalam Rajagopalan. Dated 15th November, 1946.
 Captain V. M. Rao. Dated 16th November, 1946.
 Captain B. B. Dutta. Dated 17th November, 1946.
 Captain P. C. Basu. Dated 20th November, 1946.
 Captain S. Zacharias. Dated 22nd November, 1946.

The undermentioned officer is permitted to relinquish his commission on grounds of ill health and is granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain S. C. Das. Dated 8th October, 1946.

The undermentioned officer is permitted to relinquish her commission on release from army service and is granted the honorary rank of Captain. Her services are replaced at the disposal of the Government of the United Provinces from date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain Miss Parin Tatanshah Edibam. Dated 19th November, 1946.

The undermentioned officer is permitted to relinquish his commission on reversion to the Indian State Forces :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain G. Mohammad. Dated 1st October, 1945.

RETIREMENT

Major G. W. Miller retires on account of ill health. Dated 29th December, 1945.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to 'The Indian Medical Gazette', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

POST-MORTEM APPEARANCES IN TROPICAL EOSINOPHILIA

By R. VISWANATHAN, B.A., M.D., M.R.C.P. (Lond.),
T.D.D. (Wales)

LIEUTENANT-COLONEL, I.M.S./I.A.M.C.

O/C Medical Division of an I.B.G.H.

As far as I am aware there has been no report in the medical literature of any case of death due to tropical eosinophilia. Hence the pathology of the condition has been a matter for speculation.

The following post-mortem report of a case that died of arsenical encephalopathy during the course of treatment for tropical eosinophilia should therefore be of interest.

An I.O.R., aged 28, was on active service with the Fourteenth Army for a year. During the last six months of his army life he suffered from cough with breathlessness and occasional asthmatic attacks. He was treated in the unit M.I. room off and on during the first five months of his illness. As the condition became worse he was admitted to one of the military hospitals where the diagnosis of tropical eosinophilia was made as his blood examination showed total white cell count of 28,000 with 44 per cent eosinophils. He was given two injections of N.A.B. 0.3 gm. at a week's interval. Twenty-four hours after the second injection the patient became unconscious and developed convulsions. The diagnosis of arsenical encephalopathy was made. Cerebro-spinal fluid was normal in every respects. He died 36 hours after the onset of cerebral symptoms. Just before death the total white cell count was 21,000, and eosinophils 7 per cent. As death was anticipated post-mortem examination under aseptic precautions was performed soon after death.

Post-mortem report.—The upper lobe of the left lung was adherent to the chest wall throughout its entire extent. The adhesions were recent and could easily be broken down. There was no fluid in either pleural cavity. There were dark reddish brown areas scattered over both the lungs. They were seen more extensively in the left upper lobe. Cut surface showed the same multiple dark reddish-brown areas varying in size from that of a split pea to that of a rupee. They appeared to be due to hæmorrhage and not consolidation. The affected portions of the lung did not sink in water. Some looked very much like the early stage of infarction. Bronchioles contained blood-stained mucopurulent secretion. The mucous membrane of the bronchioles was very much congested. Brain showed punctate hæmorrhages both in the white and grey matter. Mesentery showed a few areas of hæmorrhage. All other organs appeared normal to the naked eye.

Portions of brain and lung were removed under strict asepsis and sent to the laboratory for investigation.

Microscopic examination of stained section of the lung revealed the following. There were several areas of interstitial fibroblastic proliferation. Here the alveoli were lined with swollen cells and their lumina were partially or completely filled with macrophages and phagocytic monocytes. Some of these cells contained dark brown anthracotic pigment, others a small amount of hæmosiderin. But most of these cells contained eosinophilic granules grouped in one part of the cytoplasm. These granules containing cells were present in large numbers in the interalveolar spaces as well as within the alveoli. The partially consolidated areas were closely related to the terminal bronchioles. Evidence of emphysema was seen in other areas. In some of the alveoli the mononuclear cells had fused together to form very large giant cells. The nuclei varied from fifteen to twenty-five in number in each cell. They were all gathered together in the centre. In a few areas (see figure 1, plate V) a characteristic nodule formation could be seen. Each nodule consisted of four or five giant cells in the centre surrounded by a cluster of mononuclear cells. Evidence of recent hæmorrhage with marked engorgement of interalveolar capillaries was present.

The report on the samples of brain and lung tissue was as follows:—

1. Brain—Section shows congestion of brain tissue with some areas showing perivascular collection of mononuclear cells. Lung shows marked congestion, hæmorrhagic areas of bronchopneumonia and catarrhal changes in the bronchioles.

2. Rest of the tissue was emulsified separately in normal saline under aseptic precautions. The emulsions were lightly centrifuged to throw down the grosser matter and the supernatant fluid was taken out and was passed through seitz pads under negative pressure. 1 c.c. of the brain filtrate was inoculated intraperitoneally into guinea-pig no. 3. 1 c.c. of the lung filtrate was similarly inoculated into guinea-pig no. 2.

Guinea-pig no. 3 died after seven days. Post-mortem findings were:—

Stomach and intestines were empty. There was no peritoneal exudate. The heart stopped in systole, and contained no clot or blood. Lungs did not show any abnormality. Pericardial cavity did not show any exudate. Smear from the lung showed round cell preponderance and some wandering histiocytes. Some mononuclear cells showed immense phagocytosis of carbonaceous matter. A few eosinophils were also encountered.

Guinea-pig no. 2—Blood smears examined at intervals failed to show any increase in eosinophils over that seen before inoculation.

Discussion.—The hæmorrhages seen in the brain and lungs were probably due to N.A.B.

poisoning. Cellular changes in the lung are suggestive of chronicity. The affected areas are discrete and scattered. Interstitial tissue is the part mainly involved. Cellular infiltration is seen in some of the adjacent alveoli as well. The cells are mostly eosinophilic monocytes and eosinophilic polymorphs. The most interesting lesion seen is a tubercle-like nodule with a group of giant cells in the centre and a cluster of monocytes surrounding. It is definitely not a tuberculous lesion as these peculiar giant cells and mononuclears are never seen in tuberculosis. As the pathological process is in close relation to the bronchioles, it is in all probability bronchogenic in origin.

The histological changes described above make one assume that infection in tropical eosinophilia is probably by inhalation and that the infecting agent gets into the peribronchial tissue and sets up an inflammatory process involving the interstitial tissue mainly and alveoli partially. Discrete scattered areas of cellular infiltration, monocytic and eosinophilic, are produced. When the process becomes chronic nodules containing giant cells and monocytes are formed. The disseminated mottled shadows seen in the radiographs of cases of tropical eosinophilia and which last only for a short period are probably due to the areas of cellular infiltration with monocytes and eosinophiles. In some cases however the mottling lasts for months. In them the shadows might be due to the presence in large numbers of these giant cell nodules.

The histopathological appearances in this case are very suggestive of an infective process, rather than an anaphylactic reaction. The lesions are peribronchial and not perivascular.

It is extremely difficult to surmise about the nature of the infecting agent. All tests to prove a virus aetiology have been negative. The only observation which is suggestive of virus infection is the presence of perivascular cuffing with monocytes of brain capillaries. Can it be that the virus of tropical eosinophilia activated by arsenic produced the cerebral lesion?

Summary

1. Post-mortem report of a case of tropical eosinophilia is given.
2. Pathogenesis of the disease is discussed.

My grateful thanks are due to Major J. S. Greval, Officer in Charge of the Histopathological Department, Central Military Laboratory, Poona, and to Professors K. V. Krishnan and G. Sankaran of the All-India Institute of Hygiene and Public Health, Calcutta, for their help in this work.

EXPLANATION OF PLATE V

Fig. 1.—Low power. Note the tubercle-like nodule with giant cells in the centre surrounded by mononuclear cells.

Fig. 2.—High power. Oil immersion. Note the giant cells with 15 to 20 nuclei crowded together in the centre.

FOREIGN BODY LOCALIZATION : THE RING METHOD

By E. J. SOMERSET

CAPTAIN, I.M.S.

Professor of Ophthalmology, Medical College, Calcutta

IN dealing with foreign bodies in the eye or orbit it is always necessary to know as accurately as possible their exact localization. The foreign body must be localized in space in relation to the central corneal point. It will be so many millimetres above or below, so many millimetres to the temporal or nasal side and so many millimetres posterior to this central point of the cornea.

If the foreign body is in the cornea or anterior chamber or on the iris direct clinical examination will reveal its exact position. In other cases the foreign body may be observed in the lens which is as yet transparent. Finally if the lens is clear a foreign body may be seen in the vitreous or on the retina. In this case it can be localized by direct ophthalmoscopic examination. In many cases however it cannot be seen clinically. It may be behind the iris or in the ciliary body. If the lens is opaque it will be impossible to see a foreign body in the vitreous, and for its proper treatment it will be necessary to decide whether a foreign body is in the vitreous or in the retina or whether it is extra-ocular in the orbit. An attempt should always be made to remove a magnetic foreign body in the globe in order to prevent the subsequent development of siderosis bulbi. If however a metallic foreign body is outside the globe but in the orbit it may be left alone as its retention seldom produces any further damage than has already been done.

Industrial accidents and injuries with retained foreign body are common in all industrial areas and will become more common with increasing industrialization.

During the last war injuries from fragments of shell, bomb, grenade, mortar and land mines have been very common and much experience has been gained in their localization. The method most frequently used for the localization of a retained intra-ocular or orbital foreign body during the recent war has been by means of the limbal ring. This was introduced into the Middle East by Graham (Stallard, 1942) but was apparently first used by Norman in Sunderland in 1915 (Ross, 1945).

There are many methods of foreign body localization such as those introduced by Sweet, Mackenzie Davidson and Comberg.

The disadvantage of these methods are however that elaborate apparatus or complicated calculations are required, and further the ophthalmic surgeon is not always certain that accurate centering of the eye and plate has been obtained.

The contact lens method has the serious disadvantage that the contact lens often loses its

symmetrical position on the cornea during the taking of the x-ray picture which will produce fallacious results. Further, with the simple contact lens only the antero-posterior measurement is obtained.

The great advantage of the limbal ring method is that it is extremely simple, no complicated calculations are involved and the actual x-ray film shows whether accurate centering has been obtained. The only disadvantage is that a small minor operation must be performed in sewing the ring to the limbus.

Method.—After the preliminary 'straight' x-ray picture has demonstrated the presence of a foreign body a silver ring 12 mm. diameter and made of wire 1 mm. thick is sewn on the limbus with four sutures (figure 1). The usual

FIG. 1

aseptic precautions are of course taken and in most cases facial akinesia should be obtained by injection of novocaine into the facial nerve. The patient is then taken to the x-ray department and two pictures, antero-posterior and lateral, are taken. The tube should be about 30 inches from the plate so as to reduce the magnification to a minimum. The x-ray plate is placed in front of the patient's face close to the nose.

If centering has been correct the antero-posterior picture will show the ring as a perfect circle (figure 2, plate V) and the lateral picture will show it as a straight line (figure 3, plate V). If the eye has not been normal to the x-ray plate the antero-posterior picture will show the ring as an oval (figure 4, plate V) (instead of a perfect circle) while the lateral picture instead of showing a straight line will show a vertical oval shape (figure 5, plate V). The centre of the ring in the antero-posterior picture is now found either by geometrical construction or by eye. With a pair of compasses a circle is now drawn on the film whose centre is the same as the centre of the ring and whose radius is equal to the diameter of the ring, i.e. a circle is drawn on the film twice the size of the ring (figure 6). Now the actual diameter of the ring is 12 mm. so that the picture of the ring on the film (whatever the magnification at

x-ray) represents 12 mm. Thus the circle drawn on the film must represent 12×2 mm., i.e. 24 mm. diameter. Thus the outer circle

Fig. 6.

Fig. 7.

Right eye.

Fig. 8.

Fig. 9.

whatever its actual measurement on the x-ray must represent the sclera at the equator of the eye.

The actual diameter of the rings on the film is now measured and is usually found to be 13 mm. in the case of the smaller one, i.e. there is a magnification of $13/12$. The distance of the foreign body above or below the centre of the ring (central corneal point) is now measured and reduced by $12/13$. This gives the exact position of the foreign body above or below the central corneal point. Another measurement is

Fig. 10.

Fig. 11.

now made in the same way to ascertain the distance the foreign body is to the temporal or nasal side.

The lateral picture is now examined and with the compass point at the upper end of the ring (A in figure 7) an arc of a circle is described whose radius is equal to the diameter of the ring (AB in figure 7). The compass point is now placed at B and another arc of the same

radius is made to cut the former arc at C (figure 7). With the centre at C a circle is now described whose radius is equal to the diameter of the ring (representing 12 mm.) so that we now have a circle whose diameter represents 24 mm. and on which the ring (seen as a line) forms a chord. The circle thus drawn represents (whatever the magnification) the limits of the cornea and sclera seen from the lateral position. The point on the circle farthest from the ring thus represents the posterior pole of the eye. The distance of the foreign body posterior to the central corneal point may now be measured and the usual adjustment for magnification made.

The time taken to draw the circles and make the measurements is much less than it takes to write a description of them.

The measurements may now be plotted on a graph (figures 8 and 9). In most cases if the foreign body appears within the outer circle in

Right eye seen from above.

Fig. 12.

both the anterior and posterior and the lateral views it is usually intra-ocular but not always so. A horizontal projection should always be made. For example a foreign body which is 6 mm. up, 9 mm. temporal and 21 mm. posterior will appear within the outer rings in both anterior-posterior and lateral views (figures 10 and 11) but horizontal projection shows it to be outside the globe (figure 12).

Illustrative cases.—We have used this method of localization in about 50 cases and it has proved a very accurate method. The following case illustrates this :—

J. D., male, aged 25, was admitted to the Eye Infirmary, Medical College Hospital, with a history of injury by a mortar shell 12 days previously.

Examination: Right eye.—Vision, perception of light on the nasal and lower field only. Eye

quiet, no wound of entry seen. Cornea clear, pupil dilated and regular, lens clear. The vitreous was full of blood and no fundus details could be seen. The left eye was normal.

X-ray localization.—One foreign body about 2 mm. in diameter was seen to be 13 mm. to the nasal side, 13 mm. posterior and 1 mm. below the horizontal. The foreign body was thus localized to be on the sclera under the internal rectus muscle just behind the equator.

Operation was performed and the foreign body was found on the sclera under the muscle.

The case demonstrated that this method of localization can be accurate to 1 mm.

Another case is as follows:—

W. D., male, aged 27, was injured by a Japanese grenade about 70 days before being seen by us.

Examination: *Right eye.*—Vision 5/60. Cornea clear. No wound of entry seen. Eye quiet. Pupil dilated, lens clear. A yellow mass was seen on the retina at the equator in the 4 o'clock meridian. *Left eye* normal.

X-ray localization with the ring.—The foreign body (about 2 mm. in diameter) was measured to be 14 mm. posterior, 6 mm. nasal and 12 mm. below.

This corresponds with the mass of scar tissue seen ophthalmoscopically. No operation was performed in this case as the ophthalmoscopic and radiological evidence showed that the foreign body was in the scleral wall well sealed off in fibrous tissue and hence siderosis bulbi was not likely to supervene.

Comment.—X-ray of a 12 mm. silver ring sewn on the limbus is a very simple, yet very accurate, method of localizing intra-ocular and orbital foreign bodies. No complicated apparatus or elaborate calculations are necessary and the accuracy of the centering at the time of x-ray is apparent from the resulting pictures.

Summary

A description of the method of the localization of intra-ocular and orbital foreign bodies by means of the limbal ring is given and its accuracy shown by illustrative cases.

CAUSE, SYMPTOMS AND TREATMENT OF LATHYRISM

A SPECIFIC NUTRITIONAL NEUROPATHY

By H. JACOBY, M.D.

Chief Physician, Prince of Wales Hospital, Bhopal,
Bhopal State

Introduction.—There is considerable difference in the description of symptoms in lathyrism by different authors.

Shah (1939) and Minehin (1940) report, besides spastic paralysis of the legs, also involvement of the arms and sensory impairment as

well. Minehin also noted affection of the bladder. Ruge and his co-workers (1925) and Ranjan (1944) described incontinence of urine and faeces as well as sexual impairment. It has been postulated that the disease is never progressive after a few days or weeks beyond the initial paralysis (Bicknell and Preseott, 1942). Ranjan (1944), however, notes rapid progress of the disease. The published accounts of the reflexes in lathyrism are equally puzzling. Minehin (1940) observed normal eremastic and abdominal reflexes along with spastic legs and extensor plantar responses. Trabaud and Mouharram (1932) found completely normal reflexes, including the plantar responses, though there was spasticity and clonus of the legs. A common symptom associated with lathyrism is night-blindness according to McCombie Young (1928), and Ranjan (1944) reports marked dimness of vision.

Even the diseases which can experimentally be produced in animals by feeding them on certain species of legumes of the genus *Lathyrus* have also been called lathyrism, although they do not show the characteristic symptoms of the human lathyrism. Geiger *et al.* (1933) fed rats with a diet consisting of *Lathyrus odoratus*, the flowering sweet pea (at levels of 80, 50 and 25 per cent of the diet). Characteristic symptoms were lameness, paralysis and contracture of the spine and sternum. In other experiments on white rats also fed with a *Lathyrus odoratus* diet, carried out by Lewis and Esterer (1943), these authors produced a disease which they call lathyrism showing the following symptoms: Incontinence, lameness, paralysis of limbs, spinal curvature of the thoracic region. Another nutritional disease by feeding sheep with a certain species of legumes, *viz.*, cull beans, has experimentally been produced by Willman and his co-workers. They call the resulting disease 'The Stiff Lamb Disease', which shows the following symptoms: The animal concerned has difficulty in walking and rising. It gets tired very soon after walking and tries to lie down whenever permitted to do so. On standing and walking there is disturbance of keeping the balance; later on, inability to rise at all, not even with help.

Since the author is working in an area where lathyrism patients are a common sight and since all of them show a uniform symptomatology, it appears advisable to establish first of all a record of the symptoms of this disease, which we regard in this area of Central India as indispensable for the diagnosis of lathyrism.

Symptoms.—The following trail of symptoms is in our experience found in every lathyrism patient:—

1. Spastic and painful rigidity in the muscles of the lower extremity, including loin muscles. From this results a typical spastic-ataxic gait, frequently associated with a so-called scissor-gait.

2. Exaggerated deep reflexes in the legs, generally clonus.

3. The complete absence of disease-symptoms in other parts of the body, especially in the upper extremity and the head.

1. The flexor and frequently also the adductor muscles of calf and thigh, particularly the M. gastrocnemius, feel hard and are tender on squeezing. All these muscles are invariably

well developed and never flabby or atrophic. The patients complain of permanent pain in these muscles which is increased on standing and walking. In more advanced cases even the sleep is disturbed due to the pains. The examination of passive movements shows permanent muscle resistance to flexion and extension at the knee- and hip-joints. The degree of this resistance runs parallel to the advancement of the disease. In very far advanced cases the resistance is such that it is not possible at all to achieve these passive movements by force. In this late stage all such movements are possible only by the patients themselves actively, very slowly and with the help of their own hands.

Most characteristic is the gait of the patients. The onlooker gets the impression as though these patients walk against the obstacle of their own muscles. They generally walk with a slight, apparently voluntary flexion at the knee-joints, which is associated or caused by a foot-drop, in an involuntary attempt to compensate for the latter, resembling the so-called Strümpell phenomenon. Or another way of involuntary compensation is achieved by swinging the leg in a convex arch instead of lifting the foot (circumduction). The patients seem to walk on their toes only. Another group of patients who do not show the above flexion at the knees will drag the feet on the ground, as though their soles are pasted to it. These patients describe their gait themselves as 'scratching the ground'. All these symptoms which appear on walking are 'associated movements, as they are known to occur in pyramidal lesions, but are not encountered in extra-pyramidal motor lesions nor in the normal individual. These modes of walking rather belong to the advanced stages of the disease. In the initial stages only the slight muscle resistance and the slightly bent knees on walking prevail. In many cases of all stages, in whom the spasm of the adductor muscles of the thigh dominates, the so-called scissor-gait results. The patients walk with crossed legs, resembling the somewhat opened blades of scissors. The movements of the arms, normally accompanying the gait of healthy persons, are always unimpaired in lathyrism. Walking and in more advanced stages standing of these patients is complicated by a peculiar kind of swaying (ataxia). This goes frequently along with fibrillary twitchings of the muscles of the lower extremity, which in combination with the contractures result in inco-ordinated movements. This disturbance of inco-ordination of different muscle groups is certainly the cause of this particular kind of ataxia of lathyrism patients. It is not due to cerebellar lesions, because the following tests exclude this type of ataxia :—

(a) There is no 'decomposition' in the sequence of complicated single movements.

(b) The test of moving the leg and big toe away from and back to the examiner's finger as a target, with eyes shut, does not show a

deviation in any direction (Barany's Pointing Test).

(c) If the patient is made to walk forwards and backwards with his eyes shut, he will not present the peculiar deviation of the so-called 'compass gait' (Krohn, 1938).

2. The following reflex reactions are also significant of pyramidal lesion. Without exception a greatly exaggerated knee-jerk is elicited, the ankle-jerks often being diminished or absent. In some cases, however, also the ankle-jerks are exaggerated. Almost always ankle-clonus is present and frequently also 'dancing of the patella'. Far advanced cases show—on sudden brisk passive dorsiflexion of the foot to elicit ankle-clonus—an involuntary complex reflex movement consisting of flexion at the hip-joint and flexion at the knee-joint. Frequently this 'flexion reflex' occurs already by a gentle stimulus, like deep pressure or pinching of the skin of the distal part of the lower limb. Either reflex, i.e. the flexion reflex as well as the increased deep reflexes, is indicative of hyper-irritability of pyramidal origin. So is the flexion reflex a prominent feature of the usual flexor contracture (the tendon reflexes being frequently decreased) and exaggerated deep reflexes are an equally characteristic feature of extensor contracture. The latter form is indicative of a less severe lesion than the flexor contracture (Babinski). Babinski's sign by stroking the sole along the lateral border rather than the median border is as a rule extensor and signifies a less severe pyramidal affection than does an extensor response elicited from the median border as well as from the lateral border of the sole (Krohn, 1938). There is electrically no reaction of degeneration. The senses of position and of movement are always and definitely unimpaired as well as the temperature and touch senses. The Romberg sign, if positive, is of little significance on account of the above described inco-ordination of muscle movements. The superficial reflexes vary : All or some of the abdominal reflexes as well as the cremasteric reflexes are in less advanced stages normally elicitable, but are missing in far advanced cases. This pathological abdominal reflex is generally associated with the 'flexion reflex' and the extensor plantar response all belonging to the order of 'reflexes of spinal automatism' and are signs of pyramidal involvement. Anyhow, re-appearance of the previously absent superficial reflexes and of a normal plantar response and the disappearance of the 'flexion reflex' are among the signs denoting improvement under successful treatment.

3. There are definitely no abnormal nervous signs whatsoever in any other part of the body. Never was any disturbance of sensation encountered, nor of the functions of the bladder, of the bowels, of the sex and of the mentality.

Examination of the cerebrospinal fluid as to pressure, cell count, albumin content and Kahn

test shows no abnormalities. There are also no pathological findings in urine and blood. Blood pressure is normal. Radiologically, lungs and shape of the heart are always found normal.

Differential diagnosis and aetiology.—By the well-defined signs, as described above, lathyrism can be diagnosed with full certainty. There is only one other disease, the signs of which are identical with lathyrism, that is spastic spinal sclerosis of Erb (Beaumont, 1942) or the pure spastic type of amyotrophic lateral sclerosis of other authors (Price, 1941). Both diseases are caused by lesions in the upper motor neurone of the pyramidal tract. The lesion of 'spastic spinal sclerosis' is confirmed by post-mortem examinations. Records of post-mortem examinations of the spinal cord and the cerebrum of lathyrism patients appear not to be in the literature.

But the difference between these two nervous diseases does not lie in a divergence of their signs. Their only difference is the aetiology. Whereas we are not aware of the cause of spastic spinal sclerosis, the cause of lathyrism is well known, *viz*, consumption of certain species of legumes of the genus *Lathyrus* for a period of usually not less than about a month. This consumption is, therefore, to be regarded as indispensable for the diagnosis of lathyrism. We in this area of Central India found invariably that it was only *Lathyrus sativus* (teora or khesari dal) that was consumed by our patients. To the same conclusion comes also Shourie (1945) in his comprehensive review of lathyrism in Central India. This experience does, however, not exclude the possibility that other species of *Lathyrus* may also cause nutritional diseases which may more or less resemble the disease which is our subject.

Ruge and his co-workers state that besides *Lathyrus sativus*, *Lathyrus cicera* and *Lathyrus clymenum* also can cause lathyrism. But they associate with the disease disturbance of sensation, urine incontinence and impotency. Epidemics in France in 1770 and in England in 1785 were thought to be caused by eating vetches of the species *Lathyrus cicera*. This or *Lathyrus clymenum* was held responsible for an outbreak in Syria (Traubad and Moubarram, 1932), but Shah (1939), investigating an outbreak in a Punjab village in 1939, found that seeds of *Vicia sativa* and not of *Lathyrus* had been eaten mixed with corn. McCombie Young (1928), however, reports that his cases had eaten *Lathyrus* but little or no *Vicia sativa* and Minchin (1940) describes 'lathyrism without *Lathyrus*'. The latter's diagnosis appears rather doubtful in the light of our above stated experience. In connection with McCombie Young's report on *Vicia sativa* being the cause of lathyrism, examinations of *Lathyrus sativus*-stocks, as consumed by lathyrism patients, in the Imperial Agricultural Research Institute, New Delhi, failed to reveal the presence of *Vicia sativa* seeds (quoted by Shourie, 1945). The above quoted experiments on animals also show that legumes other than *Lathyrus sativus* are apt to cause nutritional diseases somewhat similar to lathyrism (Geiger *et al.*, 1933; Lewis and Esterer, 1943).

Course of lathyrism.—With regard to the onset of the disease we entirely depend on the patients' own reports. About 30 per cent of

them state that before the occurrence of the first symptoms there was fever with shivering, resembling malaria. Frequently, this statement was confirmed by malaria relapses taking place in our presence in the hospital. A minority of all lathyrism patients—less than 20 per cent—remember to have had diarrhoea previous to their falling sick from lathyrism. Actually, we found occasionally amoeba in their stools. It is, therefore, quite possible that the latter diseases acted in these cases as a conditioning cause for the deterioration of a latent background disease, *viz*, vitamin B deficiency state, on which the toxic influence of *Lathyrus* was grafted. On the other hand, the majority of our patients did not give any history of a previous disease. All our patients are, however, unanimous in their statement that the disease, generally during or after the rainy season, started slowly, at first only with heaviness in their legs, followed by gradually increasing pains in the loin, thigh and calf muscles. These symptoms deteriorate to the cripple stage, unless consumption of teora is discontinued. Even if it is continued in a mixture with wheat, containing about 50 per cent of teora, the condition goes on deteriorating. But if consumption of teora is completely stopped, the condition remains steady, showing neither improvement nor further deterioration. The latter statement of the patients could be confirmed by our own observation in the hospital; there was in a batch of eight patients neither improvement nor deterioration for a period of a month, in which no treatment was given. We must, however, mention in this connection that during this time of observation the hospital diet itself was deficient, consisting mainly of chapattis about 8 oz. and of dal about 2 oz. and occasionally of ghee 1 oz. and of milk 6 oz. per day.

Nutritional background.—Besides the consumption of a special variety of *Lathyrus*, very important for the type of symptoms appearing in different parts in the world, is in our view the nutritional background of lathyrism. Although we have not had the facility to prove this experimentally, by giving the same amount of teora to one volunteer with normal nutritional background and to another volunteer with deficient nutritional background, clinical experience shows that outbreaks of lathyrism occur at all times and in all countries only among the poor and ill-fed classes of people.

Special observations on the particular ingredient deficient in the diet are reported by McCombie Young (1928). He stresses a vitamin A deficiency among his lathyrism patients. He not only found night-blindness common in a village suffering from lathyrism, but also noticed that the disease did not occur in neighbouring villages, where the diet contained as much *Lathyrus* but more vitamin A, fish and meat; while Shah (1939) has reported great improvement in patients, when vitamins A and D were given. Apart from night-blindness no apparent deficiency diseases have been reported as occurring with outbreaks of lathyrism. A latent vitamin B₁ deficiency however is suspected as a result of the investigations on serum phosphatase of lathyrism

patients by Rudra and Bhattacharya (1946) in Patna. They found a high serum phosphatase and a consequent possible cocarboxylase deficiency in lathyrism and related these findings to the aetiology of the disease. They consider it, however, also possible that the high serum phosphatase is the effect and not the cause of lathyrism. But, of course, lack of other substances in the diet, apart from vitamins, may be important, as suggested by Basu *et al.* (1937), who found that the seeds of *Lathyrus sativus*, which often form the staple food in famine villages, are a very poor source of protein, being especially deficient in tryptophane.

The author (Jacoby, 1946) has found in this area here that the nutritional background of a vast proportion of the population is a vitamin B complex deficiency. Although symptoms of this deficiency are visible in only about 14 per cent of our lathyrism patients, the result of the therapeutic test (*see* under treatment) suggests that a latent vitamin B complex deficiency exists in a far greater proportion. It is a hitherto unexplained fact that in lathyrism villages the disease attacks generally only one or two members of a family, but leaves the others untouched who eat the same food and live under the same conditions. Children are affected roughly in the same proportion and manner as adults, but the female sex to a much smaller proportion as compared with the male sex. In Shourie's (1945) statistics only about 13 per cent were females.

Treatment.—This present description of the curative influence of prostigmin in lathyrism is based on the analysis of 50 patients treated with prostigmin.

There has been no effective treatment of lathyrism until now. Jacoby (1946a), however, discovered that lathyrism responds well to prostigmin treatment. This response differs in degree in the different stages of the disease.

The first stage in our classification comprises all those patients who can walk with slightly bent knees and only some active and passive resistance in their muscles as well as with the just noticeable scissor-gait and slight muscle pain. Their deep reflexes are, of course, greatly exaggerated, the superficial reflexes as a rule being normal and plantar response extensor, elicitable from the lateral border of the sole. No 'flexion reflex' is present. In this stage an apparently complete clinical cure is achieved through and during the treatment with prostigmin injection; in the beginning about 10 intramuscular injections of 2 c.c. are given daily, after which a course of another ten daily injections with 1 c.c. only follows. Afterwards, injections on alternate days may be sufficient to keep the achieved condition unaltered. If the treatment is discontinued, we invariably found a re-occurrence of the former symptoms. It was not possible to substitute, either for the short-term or the long-term treatment, the injections by tablets of prostigmin. The tablets have proved to be ineffective in lathyrism.

The required duration of the treatment of lathyrism with prostigmin is thus the same as in *Myasthenia gravis*. Discontinuance of the

treatment causes re-occurrence of symptoms in either disease.

The second stage in our classification of lathyrism comprises the more advanced cases with marked painful muscle spasm and a clearly visible spastic ataxic scissor-gait. Muscular fibrillations are present. These patients are still in a position to walk, although with considerable difficulty and discomfort, either just without or preferably with one or two sticks, according to the advancement of the case.

The treatment of this stage with prostigmin injections does not achieve the same result as in the first stage. The symptoms are only considerably relieved, but it is generally only possible to reach an improvement which resembles the earlier first stage in our classification. Those who were previously able to walk with the described obstacles, but without a stick, can under the influence of the prostigmin treatment walk like untreated first-stage patients, and those who required the stick are enabled to walk without it.

The third-stage patients are those who are permanently confined to bed. The muscle spasm and contractures are so extreme that they prevent practically any movement with the legs. The pains in the muscles of the lower extremity, of the calves, thighs and loins are permanent and severe. These patients have thus become cripples. At the same time all other functions of the body are unimpaired, the vegetative as well as the mental functions. The reflexes are such as we have described under 'symptoms' for the far advanced stages. The prostigmin-injection treatment in this third stage achieves little with regard to the crippled state of these patients, but succeeds in so far as the pains almost disappear and the muscle rigidity becomes less. This results sometimes in an ability of these patients to leave their bed, slowly crawling on the floor for short distances. These third-stage patients are, of course, not in a position to work. The patients, however, who belong to the first and second stage, are by the treatment with prostigmin enabled to do almost every kind of work.

The achievements under prostigmin treatment can in every case and stage be accurately checked and even measured in the following way: The exaggeration of the knee- and ankle-jerks becomes less and in early cases practically normal so that also the clonus may disappear; the extensor Babinski response in the early cases will equally approach the normal. If in the more advanced stages the superficial reflexes were not to be elicited before, they will reappear in the course of the treatment and the 'flexor reflex' disappear. The most accurate evidence of improvement is the gait, which can be measured as follows: The patient is asked to walk in his usual manner with wetted feet on the dry floor. The heel-to-heel distance is measured with a tape. This distance shows under prostigmin treatment a marked diminution

of about 3 to 6 inches. *Vice versa*, if the injections are discontinued, the length of steps slowly increases again till after about a month the original length is regained. The symptom which shows improvement last is the ataxia. It takes about 20 daily injections before the patients can for instance stand quietly on one leg, or are able to stop walking immediately on sudden order. Before the treatment they were not able to do so but had to proceed one or two steps further in order to keep their balance. The improvement of ataxia can generally not be achieved in late stages. We tried to enhance the effect of the prostigmin treatment by administering at the same time massage, light or electric treatment to the lower extremities of lathyrism patients. We did not, however, find any response to these methods.

Vitamins.—Several authors report improvement of the disease by the administration of certain vitamins. Ranjan advises plenty of vitamin A besides all other vitamins and Ahmad (1944) reports relief of pains and regained ability to walk about freely after parenteral and oral administration of vitamin B. Mellanby (1934) classes lathyrism among the deficiency diseases, since protective foods containing vitamin A and carotene, green vegetables, milk and eggs can prevent the detrimental effects of the toxic agent in the *Lathyrus* peas.

Strongly against the argument of vitamin deficiency causing the disease is the fact that in our experience the administration of vitamins in large doses does not improve the condition to any significant degree. We have tried in different batches these vitamins A and D in the form of cod-liver oil for a period of two months. We administered the vitamins B₁, B₂ complex with crude liver and the vitamin C daily by oral and parenteral route for a period of one month. But no response was ever apparent. On the other hand, we do not know of any vitamin deficiency state which does not respond at least to some extent to the therapeutic application of the deficient vitamin alone or in combination with the other common vitamins.

Another clinical evidence against the view of vitamin deficiency being the cause of lathyrism, is the feature that no visible sign of any such deficiency occurs in the bulk of our lathyrism patients. Only about 14 per cent showed symptoms of vitamin B complex deficiency in the form of a characteristic glossitis, showing also the so-called inkspots. That is a very small percentage in view of the high incidence of vitamin B deficiency states, which the author (Jacoby, 1946) found in this area. These facts show that the cause of lathyrism is surely not a deficiency of the above-quoted vitamins as tried by us therapeutically. This statement, however, is in no contradiction of the likelihood of the presence of a *latent* vitamin deficiency, forming the clinical background upon which the *Lathyrus* grain may exercise its toxic effect on the nervous system.

Two important factors have induced us to believe in the existence of such a background: firstly, the nature of food which the lathyrism patients commonly consume. They live practically on *teora* and *dal* only. Few of them can very rarely afford some milk and green vegetable also. As a rule they do not eat fish, meat, eggs and fruits. This diet resembles in quantity and quality (except for *teora*) the diet of those people among whom a great percentage in this area suffers from the different stages—latent and visible—of vitamin B complex deficiency (Jacoby, 1946). There is therefore much likelihood to presume that the majority of lathyrism patients here also live in a permanent, although invisible, i.e. latent, state of vitamin B complex deficiency.

Secondly, our practical observation at the bedside of lathyrism patients has taught us that the response to prostigmin is more immediate and more marked if vitamin B complex treatment precedes the prostigmin treatment. In a few cases this vitamin treatment seemed even indispensable to the usual prostigmin effect.

On the strength of these two clinical experiences of ours we have made it a rule to give to our lathyrism patients first a course of about 12 vitamin B complex, fortified with 1 c.c. of crude liver extract, injections before starting on prostigmin treatment.

Prevention.—It is the duty of public health authorities in all countries to prevent diseases rather than to cure them. The tackling of the disease 'lathyrism' represents such a public health problem to be undertaken by men of science in unison with the state's administrations. It seems to be a tough task, because of its manifold implications. In any case, science has given the lead in this field also by dispersing any mysticism as to the cause of this disease. To put the verdict of science in a nutshell: No lathyrism without consumption of *Lathyrus*.

The first task resulting from this scientific knowledge is enlightenment of the public. The writer has found that the villagers in lathyrism-affected places are alive to the fearful consequences of *Lathyrus* consumption. They have been taught this lesson being confronted daily with the sight of their crippled brethren who have consumed *teora*. The next task of the authorities concerned with the promotion of public health is a statistical one; a study of the incidence of lathyrism in former years and now. On the initiative of the former Revenue Minister of Bhopal State, Sir C. C. Garbett, such a study was undertaken by a nutrition expert (Shourie, 1945) for the year 1944-45. It estimated the occurrence in this district as 'at least 1,200 cases'. Since then no further statistical data have been available and the writer depended, therefore, on observations of individuals. The writer has attempted to gather such observations as originate from police officials in

charge of the villages concerned. They point to an increase in the incidence of lathyrism there during the year 1946.

Whatever significance might be given to such reports in view of the absence of official data, the writer has actually come across and treated patients whose disease represents new outbreaks in 1946. If this fact of new outbreaks in 1946 or of an increase in the incidence of lathyrism in general is recognized and appreciated by the authorities, the third task should be a legislative one. This should not prove too difficult, since this district (Bhopal) is a grain surplus area. The awareness of the villagers to the fearful consequences of teora consumption had apparently not the effect of inducing them to leave teora voluntarily to cattle only instead of using it for their consumption. They should, therefore, be prevented by law from consuming teora themselves. This ought to be a humanitarian duty and should not be governed by any other consideration. Such a step was in fact taken in November 1945 by the Department Commissioner of Jubbulpore, banning the sale of teora in the Sihora tehsil.

Along with the legal prohibition of teora consumption should go the scientific research with a view to investigating a mixture of teora mixed with other grains, i.e. mainly of wheat, in which the proportion of teora is too small to exercise its toxic effect on men. Such research, which the writer had no facilities to carry out, would be of greatest importance in view of the present world food scarcity, because it would assist in overcoming this scarcity by stretching the available food resources with the help of teora, which grows abundantly even on rocky soil in spite of hailstorm, blight, excess of rain, etc.

Summary

Lathyrism is a specific disease of the pyramidal tract, due to the consumption of teora, a species of the genus *Lathyrus*, in this area of Central India. A full account of its manifestations and a description of the treatment with prostigmin injections is given. The rôle, which vitamins, if deficient in the diet, play in the causation and treatment of the disease in men and experimental animals, is discussed. Suggestions for the prevention of the disease are made.

Acknowledgment

The author desires to express his thanks to Sir Colin C. Garbett, former Revenue Minister, Bhopal State, for his keen interest and kind encouragement throughout the work. Thanks are also due to Messrs. Hoffmann-LaRoche, Switzerland, Branch Bombay, for the liberal supply of prostigmin.

POST-MORTEM EXAMINATIONS IN THE PUNJAB : AN ANALYTICAL STUDY OF 669 EXAMINATIONS FROM 1923 TO 1944

By T. R. TEWARI
and

AMAR NATH GOYLE

(From the Department of Pathology, K. E. Medical College, Lahore)

A STATISTICAL generalization of disease incidence based on post-mortem findings has its drawbacks as well as its advantages. In India where autopsies among the not-too-poor class of patients in the hospitals and the private patients outside are 'taboo', where the subjects are mostly unclaimed bodies of beggars, vagrants and inmates of jails and asylums an adequate cross-section of the population cannot be said to come on the post-mortem table. A considerable wastage of valuable post-mortem material could be avoided and more comprehensive population groups could be studied if the pathologists were associated or worked in co-operation with the police surgeon, a practice which obtains at only a few places in India. The statistical advantage of post-mortem findings lies in the fact that the basic pathology is discovered which ultimately led to death by a terminal disease of minor import which however is more likely to be entered as the cause of death in the clinical records.

With the appreciation of the above facts an analysis of the available autopsy records of the

department of pathology of the King Edward Medical College, Lahore, is being presented. For the sake of uniformity and to facilitate comparison the investigation is much on the same lines as that of Gharpure (1927, 1928) on his Bombay material.

The sources of the material have been the general wards of the Mayo Hospital attached to the college and the Punjab Mental Hospital, Lahore. A comparison of the admission, death and post-mortem figures during the years under survey (1923 to 1944) is not very encouraging to the pathologist. The average autopsy rate works out at 5.9 per cent of the deaths. This does not compare unfavourably with the overall percentage of 4.9 arrived at by Tribedi (1941) in his analysis of autopsy figures of 10 main centres in India.

However, while the admissions to the hospital rose from 5,604 in 1923 to 9,452 in 1944 with a corresponding increase in deaths from 393 to the peak figure of 722 in the year 1942 there is no comparable increase in the number of post-mortem examinations. The autopsy percentage of deaths has ranged between 10.0 and 2.5 with the figures for the years 1939 to 1942 working out at 5.4 per cent, 3.2 per cent, 3.6 per cent and 2.5 per cent. The years 1943 to 1944 show an increase to 9.1 per cent and 8.9 per cent only because of the large number of cases referred from the mental hospital. As many as 46 and 33 out of 60 and 49 post mortems performed during the years 1943 and 1944 respectively were from the Punjab Mental Hospital. Only 14 and 16 post-mortem examinations were asked for from the Mayo Hospital during these two years out of 653 and 556 deaths giving an autopsy percentage of 2.1 and 2.8 for these years. The significant fact brought out is the progressively decreasing number of post-mortem examinations called for from the wards in spite of the increasing volume of admissions and deaths. The total period covered is long enough but the number of autopsies involved is perhaps not very large with the possibility of returning a fallaciously high percentage of some diseases while others may not be represented as adequately as they would be in a larger collection.

TABLE I

Percentage mortality according to age groups at different centres

	Lahore	Calcutta	Bombay	London
Up to 10 ..	1.2	2.5	0.78	16.9
" 11-20	16.8	13.4	10.7	10.2
" 21-30	27.6	35.3	34.2	12.1
" 31-40	26.9	27.4	28.6	12.3
" 41-50	14.8	13.3	15.8	16.5
" 51-60	8.8	5.8	7.9	20.0
Over 60	3.9	1.9	3.16	12.0
" 50	12.8	7.7	11.0	32.0
" 40	27.6	21.0	26.9	48.5

In common with figures for Calcutta and Bombay the highest death incidence is recorded in the third decade as against the sixth amongst Londoners (*see chart*). The contrast between the steep rise and fall of the curve round 30 in the Indian figures with the almost horizontal London curve from 10 onwards is well brought out in the graph. This is easily explained by post mortems in children barring foundlings being extremely rare in India and by the shorter expectation of life.

A perusal of admission and death figures during the years 1923 to 1944 shows the total admissions for Hindus and Muslims 64,056 and 79,344 respectively (the total death figures by community not being available), total post mortems amongst Hindus being 244 as against 288 amongst Muslims—a proportion roughly parallel to the admission figures. An examination of the age incidence percentage (table II)

TABLE II

Percentage mortality by community according to age groups

Age	Hindus	Muslims	Sikhs
1-10	0.45	0.45	..
11-20	6.5	5.9	0.1
21-30	10.0	10.7	0.8
31-40	9.5	10.01	1.6
41-50	3.7	6.4	1.3
51-60	2.1	3.5	0.7
61-70	0.3	1.2	0.3
71-80	0.1	0.6	0.1

of these two communities shows no difference in deaths in the earlier years of life while the Muslims provide slightly higher figures in the latter decades suggesting a possible difference

in longevity amongst the two communities. The statistical significance of the figures and the conclusion is perhaps of doubtful value but is offered as an incidental inference.

The respiratory diseases claim the largest number of deaths—nearly one-third of the total if pulmonary tuberculosis is included and one-fourth without it (table III). Deaths from tuberculosis (including pulmonary) show a

TABLE III
Percentage mortality against various disease groups

Tropical diseases	..	9.1
General	..	6.8
Tuberculosis	..	11.2
Circulatory diseases	..	9.7
Respiratory diseases	..	25.5
Nervous diseases	..	7.7
Digestive diseases	..	14.4
Urinary diseases	..	7.9
Malignant growths	..	3.1
Others	..	4.6

surprisingly low percentage in comparison with the London and other Indian figures. A conclusion that the incidence of tuberculosis in this part of the country is as low as suggested by the figures would be unwarranted for the reasons, firstly, that tuberculosis bed accommodation in the hospital during the period of survey was very small and, secondly, very advanced cases are either not admitted or removed from hospital before fatal termination.

Over 60 per cent of tuberculous disease is confined to the lungs—the commonest manifestation being a chronic fibrocaseous lesion with cavity formation (table IV). Out of 46 deaths

TABLE IV
Percentage of total mortality from different types of tuberculosis

Generalized miliary	2.9
Pulmonary	6.8
Peritonitis	0.59
Meningitis	0.59
Primary intestinal	0.1
Others	0.1

from pulmonary tuberculosis two were from acute pneumonic phthisis. In two adults the lesions were of the typical childhood type of tuberculosis with a much more marked caseous lesion in the hilar and tracheo-bronchial glands than the tuberculous focus in the lung parenchyma itself. An unusually interesting case showed in the walls of right and left auricles tuberculous masses of the size of hen's eggs with endocarditis in left auricle. There was a nodule of the consistency of a gumma on the upper

surface of the cerebellum on the right side and a smaller nodule on the anterior aspect of the left frontal lobe. The lungs and liver showed a condition of chronic miliary tuberculosis.

The incidence of deaths from tropical diseases is recorded much lower than elsewhere in India although the dysenteries account for nearly half the deaths in this group as in Bombay (table V).

TABLE V
Percentage of total mortality due to tropical diseases

Malaria	1.3
Plague	1.9
Cholera	0.1
Amoebic dysentery	1.1
Liver abscess	1.5
Bacillary dysentery	2.8
Ancylostomiasis	0.45

The bacillary would appear to be the commoner of the two dysenteries from the figures but this interpretation should be taken with reserve. It is more reasonable to take it that the acute bacillary cases come more often to the post-mortem table than the acute amoebic types and that these figures do not, therefore, reflect the relative frequency of the two diseases. The fact that more deaths are recorded from amoebic liver abscess than amoebic dysentery is a pointer in this direction.

Kala-azar and beri-beri are almost non-existent in this part of the country while relapsing fever is uncommon and cholera is seen only in epidemic form. The last case of plague post mortem was in 1926 when there was an epidemic in Lahore.

Amongst the general diseases the incidence of typhoid is high and leukaemia also shows a fairly high incidence (table VI). The lymphatic type

TABLE VI
Percentage of total mortality due to general diseases

Anæmia (including 2 cases of Banti's disease)	1.2
Leukæmia	1.04
Diabetes	0.59
Septicæmia and toxæmia	3.1
Typhoid fever	1.9

was met with more often than the myeloid in the ratio of 4 to 3. One case each of hydrophobia, blackwater fever, congenital syphilis, icterus gravis neonatorum formed part of the series. Six cases have been labelled as pernicious anæmia and two of Banti's splenomegalic anæmia. Almost 1 per cent of total mortality from this cause gives the lie to the popular belief amongst the clinicians about the non-existence of pernicious anæmia in this part of the country. These cases were diagnosed on

the basis of hæmatological findings, histamine-fast achlorhydria, neurological signs in three cases, and marked degenerative changes in the viscera. Two of these post-mortem examinations were reported by Taylor and Chitkara (1940) along with clinical reports of three other cases from their wards.

Respiratory diseases, as already pointed out, form the largest single group in the incidence of mortality and 78 per cent of this group is constituted by the pneumonias—broncho and lobar—which occur with equal frequency. No predilection was noted in the lobar type for any one lung. About 7 per cent of the deaths in this group were ascribed to pleurisy and empyema, nearly 3.5 per cent to lung abscess and 5.2 per cent to gangrene. According to these figures 9 per cent of inflammatory conditions of the lung parenchyma are likely to go on to abscess and gangrene (table VII).

TABLE VII
Percentage of total mortality due to
respiratory diseases

Lobar pneumonia	10.1
Broncho-pneumonia	9.9
Pleurisy and empyema	1.6
Lung abscess	0.9
Gangrene	1.3
Bronchitis	0.9
Others	0.7

Pericarditis is found to be the condition most frequently responsible for deaths among diseases of the circulatory system accounting for nearly one-fourth of the cases. Nearly 18 per cent of cardiovascular cases were those of endocarditis, rheumatic being twice as frequent as the other two forms of endocarditis. Thus, over 12 per cent of deaths due to cardiovascular diseases are accounted for by endocardial lesions of the rheumatic type (table VIII). This confirms the

TABLE VIII
Percentage of total mortality due to diseases of
circulatory system

Endocarditis—				
(a) Subacute bacterial	0.3
(b) Ulcerative	0.3
(c) Rheumatic	1.2
Pericarditis	2.1
Atheroma	0.4
Arteriosclerosis (renal)	0.3
Aneurysm	0.7
Syphilis	0.5
Others	4.0

clinical observations of Hughes and Yusuf (1930) and of Wig (1935) in this part of the country.

Detailed histological studies have not been made on these cases but the gross appearances and exclusion of other types of endocarditis leave

no doubt about the nature of the condition. The high incidence of pericarditis may be taken as corroborative evidence of rheumatic agency in cardiac morbidity. The combination of endocarditis and pericarditis accounting for 20 per cent of cardiovascular cases is another pointer in this direction. It may be pointed out that Kutumbiah (1940) has carried out detailed histological studies on his material in South India and produced conclusive evidence of the existence of rheumatic lesions in the heart. Rheumatism is thus shown to be not as uncommon in the tropics as is commonly believed by British workers. Atheromatous changes in the blood vessels are a common observation in most cases over thirty years of age but advanced atheromatous disease as the sole cause of death was found in only 3 out of 65 deaths from cardiovascular diseases. Aneurysmal dilatation was the cause of death in 5 cases. Rupture of the heart occurred in one case of myomalacia cordis. Two congenital abnormalities met with were one case of stenosis of the conus arteriosus and one of patent foramen ovale. Syphilitic lesions of the myocardium were seen in one case which showed fairly marked patchy fibrous scars, and perivascular round cell infiltration while aortic involvement was much more frequent.

The percentages of deaths for the digestive diseases appear rather high but this is due to the inclusion of peritonitis (non-tuberculous) under this heading. With the exclusion of these cases the percentage works out at 8.3 per cent comparable to those from other sources. The post-mortem figures bear out the extreme infrequency of peptic ulcer observed clinically in this part of the country, only one case of gastric ulcer having been encountered in the series of 669 post-mortem examinations. Cancer on the other hand is relatively less rare, there being three cases. That fatal hæmorrhage from the stomach may take place without evidence of any gross lesions in the stomach wall was our observation in one of the recent post-mortem examinations. Peritonitis alone has a death incidence of 6.1 per cent, the majority of the cases being appendicular in origin (table IX).

TABLE IX
Percentage of total mortality due to diseases of
digestive system

Peptic ulcer	0.1
Enteritis	2.5
Intestinal obstruction	1.3
Tuberculosis of intestine	0.5
Peritonitis	6.1
Cirrhosis of the liver	2.6
Others	1.3

Cirrhosis of the liver claims an incidence of nearly two and a half per cent, only one case being biliary in type for 17 of the multilobular variety. Hæmatemeses is recorded as the

commonest cause of death, hæmorrhage into the omentum occurring in one case. Affections of the respiratory tract, the kidney and the peritoneum in a descending order of frequency are the closing chapters in this condition. That more cases die of surgical conditions of the gastro-intestinal tract than of medical is a conclusion arrived at by an analysis of the post-mortem figures.

Nephritis is the most important cause of death amongst kidney diseases, about 35 per cent cardiac failure most often ringing in the curtain in these cases (table X). A little less frequent

TABLE X

Percentage of total mortality due to urinary diseases

Nephritis	2.9
Uræmia	2.0
Tuberculous kidney	0.4
Polycystic kidney	0.3
Others	2.0

is the surgical disease of the urinary tract in the form chiefly of lithiasis or obstruction from an enlarged prostate. Death from renal failure is recorded in two cases due to polycystic kidney, in one case in association with polycystic condition of the liver. The case with polycystic kidney had lived to the age of 35 years before death resulted from uræmia although the kidneys at autopsy were found to be riddled with cystic cavities containing thin watery and colloid-like material with hardly any renal tissues. Out of three cases of tuberculosis of the kidney one failed to show a tuberculous lesion elsewhere in the body.

Over 50 per cent of deaths from diseases of the nervous system are due to meningitis exclusive of the tuberculous type. Of those nearly 30 per cent are meningococcal while the remaining are metastatic infection or the result of spread from contiguous lesions mostly in the middle ear. Syphilitic meningitis is recorded once in thirty-one cases of meningitis as also one case of gumma of the brain in the whole series. Cerebral and cerebellar cyst and abscess, meningioma,

TABLE XI

Percentage of total mortality due to diseases of the nervous system

Meningitis	4.0
Apoplexy	1.6
Extracerebral hæmorrhage	0.59
Syphilitic meningitis	0.1
Transverse myelitis	0.3
Encephalitis	0.1
Others	1.03

hæmorrhage of the pituitary and encephalitis were recorded once each in the whole series (table XI).

Malignant disease is responsible for 3.1 per cent of the deaths having been encountered 21 times in the present series of post mortems. The possibility of fallacy from an unreserved generalization from post-mortem figures is well illustrated by the fact that not one of these cases was cancer of the uterus or breast. The only case of breast cancer died of secondary growths in the skull bones and dura mater eight years after mastectomy without any local recurrence. It must however be remembered that the females provided just about 6 per cent of the post-mortem material under investigation. Over 57 per cent of the malignant growths were in connection with the gastro-intestinal tract, the stomach being the site most often involved (table XII).

TABLE XII

Percentage of total mortality due to malignant growths

Cancer liver (secondary)	0.7
Cancer stomach	0.4
Cancer cæcum	0.3
Cancer œsophagus	0.1
Cancer lung	0.1
Malignant melanoma (rectum)	0.1
Malignant endothelioma (peritoneum)	0.1
Malignant papilloma	0.1
Retroperitoneal sarcoma	0.1
Lymphosarcoma	0.1
Sarcoma rib	0.1
Hypernephroma	0.1
Cancer breast (secondary deposit in skull)	0.1
Cancer prostate (secondary deposit in colon)	0.1
Teratoma testicles (secondary deposit in lung)	0.1
Glioma motor cortex	0.1

Secondary growths were present in the liver in almost all these cases. No proved case of primary carcinoma of the liver was found in the series. The only teratoma met with was found associated with secondary deposits in the lungs.

A case of unusual interest in the series was one of complete transposition of viscera, both thoracic and abdominal.

Summary

An analysis of 669 post-mortem examinations carried out in the Pathology Department of the K. E. Medical College, Lahore, during the years 1923 to 1944 is presented. The inadequacy of autopsies in spite of the increasing admissions and deaths in the attached hospital is commented upon.

The incidence of mortality is distributed as follows:—

General diseases 7.9 per cent, tropical diseases 7.9 per cent, circulatory diseases 9.7 per cent, respiratory diseases 25.5 per cent, nervous diseases 8.6 per cent, digestive diseases 13.0 per cent, urinary diseases 7.9 per cent, tuberculosis 11.2 per cent, and malignant growths 3.1 per cent.

Respiratory diseases are responsible for the highest mortality. Nearly 35 per cent of deaths from kidney diseases are due to nephritis.

Pernicious anæmia is shown to be not as rare in this part of the country as believed.

Peptic ulcer is extremely uncommon.

Kala-azar and beri-beri have not been met with in the whole series.

Incidence of deaths from tuberculosis is recorded low and reasons are given for it.

Malignant growths in the series have been found most common in the gastro-intestinal tract.

PREDIGESTED PROTEIN FOODS

By K. V. GIRI
 S. KUPPUSWAMY

and

V. SUBRAHMANYAN

*Department of Biochemistry, Indian Institute of Science,
 Bangalore*

IN recent years, the nutritive value of predigested protein foods is attracting widespread interest among nutritionists. In view of the present scarcity of good sources of protein, such as meat, eggs and milk, consideration must be given to the value of other protein foods to feed the population and specially for rapidly restoring the badly undernourished millions at the present moment of food crisis. It is a well-known fact that sufficient protein must be taken along with our food in order to meet the normal requirements of the body to maintain proper health. The ingested protein must be broken down by hydrolysis in the digestive tract before it can be absorbed through the gut. The physical condition of a food may, however, prevent the digestive juices from penetrating to the proteins and acting on them. If, therefore, the proteins are broken down by enzymes outside the body, they would be more completely utilized. Further, it is known that certain amino-acids and peptides act as co-enzymes for proteolytic enzymes which are responsible for the digestion of proteins. Thus, if the preparation contains hydrolysis products also, i.e. amino-acids and peptides, these digestion products activate the enzymes, thereby augmenting the digestive capacity of the juices. In fact, amino-acids are necessary for certain enzymatic reactions to take place.

In cases of starvation, sufficient food is not available for meeting the normal bodily requirement. The body reserves are so depleted that they adversely affect the proper functioning of the digestive enzymes. This extreme state of disturbance in normal digestion and metabolism leads to diarrhoea and subsequent death. It is

now claimed by many workers that treatment with predigested protein food results in dramatic improvement in such cases. In addition to its value in the treatment of cases of starvation, it has proved a valuable food for premature infants and children with digestive disorders and in the treatment of gastric ulcers. It is also invaluable as an easily assimilable protein food for infants, invalids and as a general protein supplement for even normal persons. It is the object of the present note to review the available literature relating to the use and value of the various preparations of predigested protein products in nutrition and medicine and to evaluate the experience of other workers in the use of the products together with a brief description of the preparation of such products from vegetable sources.

Treatment of malnutrition.—A form of predigested food known as 'F-Food' or famine food containing amino-acids, glucose and vitamins has been used for feeding the starving population of the liberated European countries. Recently, protein hydrolysate products prepared from edible meat was used in the treatment of extreme cases of starvation in the Bengal famine of 1943, where even intravenous glucose administration was of no use (Mukerji, 1945).

Other uses.—Patients who have been deprived of nourishment because of carcinoma of the stomach or some other gastric disorder have been successfully treated in America by intravenous injection of hydrolysed casein. It is also being administered to patients in order to hasten the regeneration of blood plasma after severe loss of blood from war wounds. These preparations, therefore, are likely to form part of the routine hospital treatment of cases in which there is a deficiency of plasma protein.

Feeding of premature or undernourished babies.—Preparations of hydrolysed casein are now being used for the feeding of premature or undernourished children. Although human milk is superior to all other foods for growing children, it is not the ideal nourishment of infants who have begun their extra uterine life too early. Further, the high calorie requirements of these infants together with the lack of proper functioning of their digestive organs, make it necessary to supplement breast milk—which on account of its low caloric value places a high demand on the digestive organs—with other foods which are easily assimilable and rich in protein. Recently, highly significant results have been obtained by the use of amino-acid mixtures as additional food for premature infants (Magnusson, 1944). A mixture of amino-acids obtained by enzymatic digestion of casein mixed with glucose to supply calories and salt mixture to meet the salt requirements is found to be the ideal food for premature infants. A comparative study of the increase in weight of infants by feeding undigested casein on the one hand and amino-acid mixture on the other has shown that the gain in weight was considerably

greater when amino-acid mixture was being administered. The preparations used in these studies had the following composition:—

Amino-acid mixture ..	25 per cent
Glucose ..	25 per cent-
Salt mixture ..	1.5 per cent

The mixture was given through a catheter along with breast milk during first few days of life and later fed by mouth. The preparations are stated to be well tolerated by infants without any complications such as vomiting or digestive disturbances.

'Protein hydrolysate' preparations.—Predigested foods consisting of 'protein hydrolysates' are now being manufactured by a number of pharmaceutical firms in America. A brief description of these products with their methods of preparation may be of interest.

The preparations as at present used are of two kinds: (1) a solution of amino-acids prepared by acid digestion or enzymic digestion of protein, particularly casein, for intravenous use, and (2) preparations obtained by digesting protein (casein or meat) with enzymes, which contain amino-acids, peptides and also peptones and albuminoses for oral use. These preparations are frequently used admixed with glucose and vitamins in feeding the starving population of some of the liberated European countries.

The disadvantage of acid digestion process is that tryptophane is destroyed during the process, and therefore it should be replaced by adding tryptophane to the final product. On the other hand, in the enzymic digestion process the tryptophane remains intact. The predigested food which, otherwise known as 'F-Food' which has been in use in Europe, is a mixture of amino-acids, glucose and vitamins. It is stated that two litres of the product is equivalent to about 50 gm. of protein.

Other types of preparations which are intended for oral administration consist of spray-dried solid material obtained by digesting casein or meat with enzymes. These preparations contain mixtures of amino-acids, peptides and peptones. Vitamins can be added to this powder. It is generally administered by mouth or by stomach tube.

Preparations used during the last Bengal famine of 1943.—The preparation of protein hydrolysate product from edible meat, rich in amino-acids, has been described by Mukerji (1945). This preparation was used during the last Bengal famine of 1943 for treatment of cases of starvation. Highly successful results were obtained during the famine period. In view of its valuable therapeutic properties and its regular use by the medical profession, the author has described certain sets of standards to be followed by all pharmaceutical concerns taking up the manufacture of this product, and a tentative monograph on the subject drawn up in accordance with the B.P. is given. This

preparation is intended for intravenous administration. The method of preparation is described.

New sources of food protein.—The protein hydrolysates described above are generally prepared from casein or meat. In view of the present scarcity of animal products, it is necessary to find adequate alternatives. Increased interest has recently developed in the nutritive value of plant proteins which may partially replace or substitute proteins of animal origin. Various oil bearing seeds can be used as a source of food protein after extraction of oil, e.g. groundnut, sesame and coco-nut.

Groundnut is rich in high class protein. In addition, it is a rich storehouse of vitamins, particularly vitamin B₁ and nicotinic acid. At present, the cake after removing the oil by mechanical expression is used largely as food for animals and as manure. The utilization of this by-product of the groundnut oil industry as food material for humans has not been feasible, because it is lacking in certain qualities. A process has been developed in these laboratories for the preparation of predigested food from groundnut cake.

Groundnut cake is finely powdered and passed through a 40-mesh sieve. To one part of the powder about 4 parts of water are added and brought to a temperature of 70 to 75°C. A solution of papain is added to the suspension and digested for 4 to 5 hours. The whole mass is then filtered in a filter press and the filtrate is concentrated to a moisture content of 20 to 25 per cent. The concentrate is then steamed at 5 pounds pressure for half an hour and stored in stoppered bottles. This method of obtaining the predigested protein food results in a product containing the bulk of protein, vitamins and minerals originally present in the cake. The product is palatable and thus aids in its general acceptance. The residual material obtained after extraction of the hydrolysate contains some quantity of undigested protein, carbohydrates and minerals which could be used as a stock feed after drying.

The following is the analysis of the product obtained from groundnut cake after processing:—

Chemical composition of predigested protein food from groundnut cake

Water ..	25.7%
Total nitrogenous extractives ..	60.8%
Non-protein nitrogenous extractives ..	46.6%
Proteoses ..	32.2%
Peptones ..	9.9%
Amino-acids ..	4.5%
Amino nitrogen as per cent of total ..	11.8%
Ether extractives ..	0.24%
Ash ..	4.12%
Phosphorus ..	0.336%
Calcium ..	0.068%
Iron ..	0.0064%
Vitamin B ₁ ..	8-10 µ g./gm. (260-330 I.U./100 gm.).
Nicotinic acid ..	290 µ g./gm.

The analysis shows that it contains 55 to 60 per cent of proteins and their breakdown products. Four teaspoonfuls (drachms) will contain about 6 gm. of protein (which is about the same amount of protein as present in one egg or 1 oz. of meat) in a completely predigested form.

The predigested protein concentrates from groundnut cake offer a good substitute for meat and meat products. A suitable mixture of groundnut, cottonseed and sesame flour, predigested and concentrated, would certainly turn out to be a first-class article of food.

MALE HORMONES FOR THE PREVENTION OF RELAPSES IN MALARIA

By S. J. GROSS, M.D.

Medical Superintendent, Baer Hospital, Chirala, India

A NUMBER of methods and of drugs are employed in the after-treatment of malaria with the aim to prevent relapses. The known antimalarial drugs are unable to do so; in fact, some of the drugs have also the property to precipitate a relapse. I used salvarsan for some time with quite satisfactory result but gave it up when I had a relapse which proved fatal. Therefore, I was looking for some measure which would not be provocative and would be of value in the prevention of relapses.

I could observe in a number of patients who had frequent relapses that these relapses recurred at regular intervals, so that the next attack could be predicted accurately. A regular interval between the relapses has also been observed by Noe, *et al.* (1946) in chronic south-west Pacific malaria, and Nocht and Mayer (1937) described periodical relapses after three weeks. In my cases the interval was between three to four weeks.

The regular recurrence made me suspect that in these cases some cyclical activity of the body might be responsible for the precipitation of the relapses. The interval of about four weeks—or a multiple thereof—points to the menstrual cycle as the periodical activity eventually responsible for the recurrence. Closer scrutiny of ætiological and of clinical features reveals a number of facts which indicate the participation of female or oestrogenic factors in the mechanism of malaria. The following facts seem significant:—

1. Malaria is transmitted by the female anopheles only.

2. It has been observed by many authors that female gametocytes are more numerous in the blood than male gametocytes; female gametocytes have been found to predominate in the relation of from 3 to 1, up to 6 to 1.

3. It is stated that in relapses chiefly female forms are seen in thick drop preparations (Nocht and Mayer, 1937).

4. A great incidence of abortions and of premature births in women suffering from malaria has been observed by many authors. In this connection it may be recalled that administration of œstrin during pregnancy may lead to abortion.

5. Malaria is said to cause impotence, sterility and frigidity in a number of cases. Animal experiments have shown that injections of œstrin will lead to change of the sex characteristics, and may eventually cause atrophy of the gonads.

6. It is generally stated that women are possibly more susceptible than men to malarial infection.

In view of the above facts I concluded that the inhibitory effect of male hormone might help to suppress and to counteract those factors which are responsible for the periodical relapse. Administration of testicular hormone has the effect that follicle maturation and luteinization are suppressed, the vaginal changes of œstrus are absent, and that menstruation (in monkeys) is completely inhibited.

For the present investigation only cases of *vivax* infection were selected, as these have a greater tendency for relapses. One week after routine treatment of the attack nine of these patients were given four injections of perandren (testosterone propionate) on alternate days. The patients have been under observation for a period of 6 to 8 months after the administration of perandren. During this period all of these cases had an inoculation with T.A.B. vaccine which could have provoked a relapse. None was seen after the inoculation. One of the nine patients had a true relapse, while two had 'relapses' of an unexpected nature during the period of observation. A short description of some of the cases is given below:—

1. C. A., male, 46 years old, had his first attack of malaria in 1944. Patient had also a syphilitic infection, and therefore he was allowed to have a number of fever bouts before treatment was given. In spite of simultaneous arsenic treatment, patient had a number of relapses. After his last relapse on 2nd October, 1945, he was given four injections of testosterone propionate one week after treatment of the relapse. On the 2nd November, 1945, he returned to hospital with another relapse. On each occasion *P. vivax* rings were found in the blood.

2. V. C., male, 32 years old, had attacks of malaria in July and August 1945. On each occasion *P. vivax* rings were found in the blood. On 23rd September, 1945, he had another relapse. After treatment of the relapse he was given four injections of testosterone propionate. On 24th October, 1945, he returned to hospital complaining of chills. A blood slide was taken which showed *P. vivax* rings. However, the

chill was not followed by any rigor or fever, and patient left hospital after a few hours. Before leaving hospital he was given another injection of 10 mg. of perandren. 48 hours after the first chill, patient returned to hospital with chills, and this time it was followed by rigor and fever. Another slide was taken, and it showed now only *falciparum* rings. Further course was uneventful, and the patient has not had any further relapse since.

3. B. C., male, 39 years old, had a massive and serious *vivax* infection on 31st August, 1945. After treatment of the attack he was given 40 mg. of male hormone. He returned to hospital on the 24th December, 1945, complaining of chills. Temperature was 98.6°; a smear was taken and showed *falciparum* rings only. The chill was not followed by any fever, and the patient left hospital without having any further treatment. Subsequently he did not develop any further chills, nor has he had any relapse since.

4. D. E., male, 30 years old, had an attack of *vivax* malaria on 8th September, 1945. He was readmitted with a relapse on 5th October, 1945. On admission he had a slight temperature, chill, pains in the joints and abdomen. The next day he was given an injection of male hormone in addition to mepacrine tablets. On the 7th afternoon he had a fever paroxysm of 104°. After this attack of fever the patient had no further paroxysm, nor was any provoked by the other injections of perandren which were given subsequently on alternate days. Patient has not had any relapse since.

In none of the other five cases was there any relapse after the injections of male hormone nor was there any untoward reaction.

Comment.—Only one out of nine cases of relapsing malaria which were given perandren injections as after-treatment had a real relapse. Two other cases had chills, but no fever, though parasites were found in the blood smear. It is noteworthy that when male hormone was given in the preliminary stage, as in cases 2 and 4, this was followed by a fever attack; however, the patient had no paroxysm thereafter. No fever was caused by the injections of testosterone propionate in those cases which were injected one week after the actual attack.

It has to be mentioned that all patients felt much better after the injections of male hormone, and that they had a speedier recovery from the debilitating effects of the malaria attack. This may be attributed to the tonic effects of testosterone propionate. Korenchevsky *et al.* (1941) investigating the effect of testosterone propionate on liver, kidney and heart found that it possesses hepatotropic, nephrotropic and cardiotropic effects.

The number of cases is admittedly too small to draw any definite conclusions, but the results seem of sufficient interest, so as to warrant further investigations. It is possible that the dosage used in the present series was too small

and that larger doses, e.g. six injections of 25 mg., might be given.

I want to thank Messrs. Ciba (India) Limited for the supply of perandren.

THE TREATMENT OF INTESTINAL WORMS WITH THE INDIGENOUS DRUGS BUTEA, EMBELIA AND KAMALA*

By A. K. MUKERJI, M.B.

and

N. V. BHADURI, M.Sc., M.B.

Department of Helminthological Research, Calcutta School of Tropical Medicine

THE indigenous drugs Butea, Embelia and Kamala have been used in India as anthelmintics from ancient times and they were even included in the *British Pharmacopæia* for some time. Although the authors of books dealing with the indigenous drugs speak highly in general terms of these three anthelmintics, in only one instance do we find that any facts and figures have been given. Caius and Mhaskar (1921, 1923) treated 32 cases of hookworm infestation with a single dose of 10 to 40 grs. of powdered Butea seeds; only a small number of hookworms were passed, and no case was cured microscopically. With the same dosage only 2 out of 26 cases of ascariasis were cured. Embelia given in 2 to 4 dr. doses in a single administration was ineffective in 24 cases of hookworm, and in 4 dr. doses in 8 cases of ascariasis. Kamala was similarly ineffective in 1 to 1½ dr. doses in 7 cases of hookworm infestation and in 2 dr. doses in 3 cases of ascariasis.

Chopra (1933) stated that 'fresh seeds of Butea, ground in the form of a powder, proved to be very efficacious in ascariasis, almost at par with santonin in a series of 30 cases, whilst in another series, the results were disappointing'.

Having seen in Sanskrit literature that the combination of these drugs was sometimes prescribed, we decided to try these drugs again individually and in combination with one another.

Methods of Administration and Dosage

Fresh seeds of *Butea frondosa* (Beng.—Palash) and the dried fruits of *Embelia ribes* and *E.*

*The work reported in this paper was undertaken under the Endowment Fund of the Calcutta School of Tropical Medicine, aided by a grant from the Indian Research Fund Association.

robusta (Beng.—Biranga or Baberung) were purchased locally and ground up finely. Kamala, the minute red glands and hairs of *Mallotus philippinensis*, was available as a coarse powder but it was also ground up finely.

For the treatment of hookworm and ascaris infestation, no preliminary purgative was given. The drugs were mixed with sugar and water into a paste and administered either at bed time into a paste and administered either at bed time three hours after the last meal of the day or in the early morning before any food had been taken (marked as 'single doses' in the tables). In some instances two doses were given, one at bed time and another early the next morning (marked as 'double doses' in the tables). When the drugs were given at bed time, a dose of sodium sulphate solution was given the next morning and two hours after the morning dose of the anthelmintic in other instances. No food was allowed till the bowels were moved satisfactorily. To ensure bowel movements the dose of sodium sulphate was repeated, if necessary, after two hours. When the drugs were given daily for more than one day, sodium sulphate was given at the end of the treatment.

For *Tania* and *Hymenolepis* infestations a preliminary purgative was given in every instance.

The age of the youngest patient in our series was 4 years. We found that children below this age could not swallow the drugs properly. Some of the older children and a few adults vomited either soon after taking the dose or later after the dose of salts. Most of the patients, however, retained the drugs and did not complain of any abdominal pain or show any untoward symptoms.

For children up to 12 years, 8 to 30 grs. of each drug according to age was given, for adolescents 40 to 45 grs. and for adults 60 grs. or more.

The preliminary diagnosis was made by finding of ova (or segments in the cases of *Tania*) in the stools examined by large smear method and also by Lane's Direct Centrifugal Flotation (D.C.F.). It was not possible to count the worms passed after the treatment as many of the patients were treated in the out-patients' clinic. In the case of the in-patients, hookworms were occasionally seen and ascaris in many. For the criterion of cure, we depended upon the disappearance of the ova from the stools examined by the two methods mentioned above at least ten days after treatment. For cases of *Tania* infestation, we followed up the cases, and if segments reappeared in 6 to 12 weeks, these were marked as 'not cured'. We may mention here that we examined the stools of many cases of taeniasis in our series for three days after treatment, but no scolex was found in any of them.

A small number of patients, not cured by one treatment, was given a second and third treatments at an interval of 10 to 15 days.

Hookworm

The results of treatment with the different drugs are shown in table I:—

TABLE I

Dose in grains	Frequency	Number treated	Number cured
<i>Butea</i>			
15-30	Single	8	1
60	"	20	0
120	"	4	0
10	T.d.s. for 3 days	1	0
<i>Embelia</i>			
60	Single	2	0
120	"	1	0
180	"	8	1
<i>Combined Butea and Embelia</i>			
15 each	Single	3	1
20 "	"	5	1
20 "	Double	5	1
30 "	Single	14	0
30 "	Double	3	0
40 "	Single	2	1
45 "	"	7	3
60 "	"	22	1
60 "	Double	2	1
90 "	Single	24	0
120 "	"	41	2
150 "	"	13	1
180 "	"	7	1
20 "	Once daily for 6 days	1	0
20 "	T.d.s. for 3 days	4	0

Results of second and third treatments.—Eight cases were given single doses of *Butea* with one cure; two cases were given a third treatment—no cure. Two cases were given *Embelia* (single dose) with one cure. With combined *Butea* and *Embelia* 2 out of 22 were cured after second treatment, and 1 out of 5 after third treatment. (One patient was given a fourth treatment with a single dose of combined *Butea* and *Embelia*, but even then he was not cured.)

It will be seen from table I that the drugs have no appreciable effect against hookworms.

Ascaris

The results of treatment of ascariasis are given in table II:—

TABLE II

Dose in grains	Frequency	Number treated	Number cured
<i>Butea</i>			
8	Single	1	0
15	"	2	0
18	"	3	0
20	"	1	1
22	"	6	0
24	"	3	1
28	"	5	1
30	"	3	1
60	"	10	7
120	"	2	1

TABLE II—concl'd.

Dose in grains	Frequency	Number treated	Number cured
<i>Embelia</i>			
30	Single	2	0
60	"	5	1
60	Double	1	0
90	Single	1	1
120	"	2	1
180	"	1	1

Combined Butea and Embelia

10 each	Single	5	1
15 "	"	3	0
15 "	Double	7	1
20 "	Single	13	3
20 "	Double	23	1

90 "	Double	2	1
120 "	Single	31	17
150 "	"	5	4
180 "	"	2	1

Combined Butea, Embelia and Kamala

10 each	Single	4	1
15 "	"	2	0
20 "	"	7	1
30 "	"	6	0
60 "	"	6	3

Results of second and third treatments :—

Butea

Second treatment: Six cases given 15 to 30 grs. (single)—not cured; two cases given 60 grs.—both cured.

Third treatment: Given to two cases (22 and 28 grs.)—not cured.

Combined Butea and Embelia

Second treatment: 20 to 30 grs. of each given to twenty cases, 2 cured; 40 to 45 grs. given to 5, 2 cured; 60 to 120 grs. given to 8, 6 cured.

Third treatment: 15 to 30 grs. (double) given to 4, one cured.

Combined Butea, Embelia and Kamala

Second treatment: 10 to 30 grs. of each given to 4, none cured.

Third treatment: 10 grs. of each given to 1—cured.

It will be seen from table II that the cure rate was better with the larger doses than

with the smaller ones. The result from this point of view is shown in table III :—

TABLE III

Drug	Dose in grains	Number treated	Number cured
Butea	8-30	24	4
	60-120	12	8
Embelia	30	2	0
	60-180	10	4
Combined Butea and Embelia.	10-30	111	17
	40-45	24	7
	60-180	97	47
Combined Butea, Embelia and Kamala.	10-30	19	2
	60	6	3

With doses of 60 grs. and more, Butea and Embelia have definite ascaricidal properties. (We did not try Kamala alone for either hook-worm or ascaris.)

About half the number of cases were cured by one treatment with 60 grs. or more of these two drugs either singly or in combination.

The cure rate compares very favourably with that of santonin and oil of chenopodium. Maplestone and Mukerji (1931) treated 90 cases with one dose of santonin curing 31 cases only. With oil of chenopodium, 37 were cured in a series of 67 cases. Butea and Embelia and therefore better than santonin and equally as effective as oil of chenopodium for ascaris.

Tania

Altogether 56 cases were treated by the different drugs. As we had to depend upon the after history to find out the end-result, we tried to follow up all these cases, but we succeeded in 34 cases only. The result of the treatment of these 34 cases are shown in table IV :—

TABLE IV

Drug	Dose in grains	Frequency	Number treated	Number cured
Embelia	60	Single	6	0
		Repeated after one hour.	2	1
	120	Single	4	1
		Repeated after one hour.	1	1
	180	Single	4	0
		"	"	"
Combined Butea and Embelia.	90 each	"	1	0
	120 "	"	2	0
	180 "	"	1	0
Combined Embelia and Kamala.	30 "	"	1	0
	60 "	"	2	0
	90 "	"	1	0
	120 "	"	9	0

A second treatment with *Embelia* was given to 2 patients (60 grs. and 120 grs. single doses respectively) but still they were not cured. Similarly combined *Embelia* and *Kamala* (single doses of 120 grs. each) failed in 2 cases. None of these drugs, therefore, appear to have any appreciable effect in *Tania* infestations.

Hymenolepis nana

Out of 30 cases treated, only one was cured as will appear from table V :—

TABLE V

Drug	Dose in grains	Frequency	Number treated	Number cured
Butea	60	Single	2	0
Embelia	120	"	4	0
Kamala	30-120	"	6	0
	10-20	T.d.s. for 3 days	4	0
Combined Butea and Embelia	20 each	Once daily for 3 days	1	0
	30 "	Single	2	0
Combined Embelia and Kamala	10-30 "	T.d.s. for 3 days	2	0
	30 "	B.d.s. for 3 days	1	0
	30 "	Single	1	0
Combined Butea, Embelia and Kamala.	15-60 "	"	7	1

Discussion of Results

It is evident that these drugs have little effect against hookworm, *Tania* and *Hymenolepis nana*, but Butea and Embelia have decided ascaricidal properties. The doses of these drugs, however, cannot be reduced proportionately for children without lowering of their anthelmintic action. This fact was also noted by Maplestone and Mukerji (1938) in the case of oil of chenopodium for treatment of ascariasis in children. The explanation offered was that the worms were just as large in children as they were in adults—hence the smaller doses failed to clear them out. On the other hand it might be argued that the smaller volume of the child's intestine should give a concentration of the drug in a reduced dose approximately equal to that given by a full dose in the intestine of the adult. Another explanation offered was that the majority of the intestinal helminths more readily infected younger animals than adults, so the power of these worms of maintaining themselves was greater in the more susceptible child than it was in the more resistant adult—hence they are not so easily dislodged from the former as they are from the latter by the same treatment. We are inclined to believe that the lowering of effect caused by the reduction of the dosage of Butea and Embelia for children is due to this factor.

One disadvantage is the bulk of these drugs. This can be rectified to a certain extent by making compressed tablets.

The main advantage, however, lies in the cost; one dose of two dr. of the drugs costs less than one pice (at the current price of As. 10-0

per lb.); one 3 gr. dose of santonin costs 3 annas (at the current price of Rs. 27-0-0 per ounce) and one 1.5 c.c. dose of oil of chenopodium costs about 2 annas (at the current rate of Rs. 32-0-0 per lb.). Moreover, the ascaridol content of oil of chenopodium is liable to deteriorate in the tropics as shown by Mukerji and Sen Gupta (1945). Butea and Embelia are, therefore, efficient and cheap substitutes for santonin and oil of chenopodium in the treatment of ascariasis.

Summary

1. The indigenous drugs Butea, Embelia and Kamala were tried in hookworm, ascariasis, *Tania* and *Hymenolepis* infestations of man.
2. These drugs have no effect on hookworm and tapeworm.
3. Butea and Embelia are better than santonin and equally as good as oil of chenopodium in the treatment of ascariasis.

PAUL-BUNNELL TEST IN THE DIAGNOSIS OF GLANDULAR FEVER WITH REPORT ON SEVEN CASES

By D. W. SOMAN

Haffkine Institute, Bombay

GLANDULAR fever, which is synonymous with infectious mononucleosis or monocytic angina, is an acute, febrile, infectious adenitis with a characteristic increase of mononuclear blood cells. Clinically, the most impressive features of this disease are its protean manifestations, its extremely variable severity and its almost

invariably favourable termination. Numerous epidemics have been described; the degree of contagiousness is probably low. Sporadic cases are frequent. The disease is widely spread but no authentic case of this disease has been recorded in India according to Tidy (1937) and no such case has been reported even to this date. The present communication is, therefore, intended to draw the attention of members of the medical profession to this clinical condition, a few cases of which have been clinically diagnosed and confirmed by carrying out Paul-Bunnell tests at this Institute. The test is based on the accidental discovery by Paul and Bunnell (1932) that the blood serum in glandular fever contains heterophile antibodies in the form of an agglutinin for sheep's red cells. Many forms of this disease, not previously recognized, have been identified with the help of this test. It has been found that certain other conditions may give a positive Paul-Bunnell test and the most notable of these is serum-sickness. Further studies by Stuart *et al.* (1934), Bailey and Raffel (1935), Davidsohn (1937), Barrett (1941) and Kilham and Steigman (1942) have shown that the normal heterophile antibody from the serum can be completely absorbed by the guinea-pig kidney, that that met in serum-disease can be absorbed by guinea-pig kidney and ox erythrocytes and that the heterophile antibody of glandular fever can be absorbed by ox corpuscles but not by guinea-pig kidney (table I). The absorption test is very useful when serum-sickness cannot be excluded as well as for identifying significant low titre reactions.

During the year 1944, a request from the medical officer of the Royal Naval Hospital in Bombay for performance of Paul-Bunnell test, on the sera of their patients, led the author to utilize this opportunity to carry out this piece of work. As these tests were rarely asked for by the medical profession in Bombay, and that has been the experience of the author for the last five years, such tests were not carried out at this Institute as a routine. Under the circumstances it was thought desirable to establish first the minimum diagnostic titre by estimating the level of sheep cell agglutinins in the sera of normal and healthy individuals from hospitals and private practitioners. Accordingly Paul-Bunnell tests were done on 300 random samples of sera received for Wassermann test. Three hundred samples of Widal sera were also done with a view to detecting if any cases of glandular fever were missed. The number of samples of sera specifically sent for the diagnosis of glandular fever were 64 out of which 53 were received from 44 cases in the Royal Naval Hospital.

Technique

Several methods of performing the Paul-Bunnell test are in vogue, the variations being confined mainly to the amount of serum used

and to the strength of sheep cell suspension. In all methods it is essential to inactivate the serum first by heating at 56°C. for 20 minutes and to use sheep cell suspension which is not less than 24 hours old and not older than 5 days. In addition, the work of Stuart, Burgess, Lawson and Wellman (1934) showed that there is no general agreement in the literature concerning sheep cell agglutination titres of normal people and that the titre depended on such factors as the temperature at which the test is performed, the concentration of the sheep cells employed and the expression of the titre in terms of final concentration of serum after the addition of sheep cells. Therefore, no statement of sheep cell agglutination titres is of value without information concerning the exact technique.

The technique adopted was as follows—A series of doubling dilution of the inactivated serum was made with saline starting with 1 in 5, with 0.5 c.c. of the diluted serum in each tube of an internal diameter of 9 mm. To each of these tubes was added an equal amount of 1 per cent suspension of sheep cells in physiological saline. The cells were thrice washed with the physiological saline and the hæmatocrit of a concentrated suspension was determined and the amount of saline necessary to give 1 per cent of suspension was added. The final serum dilution, after the addition of sheep cells, therefore, ranged from 1 in 10 to 1 in 2,560. The test rack was incubated at 37°C. for two hours and the results were read after shaking until all the sediment was evenly suspended. Three grades of agglutination were recognized, firstly, all the cells remaining in one solid clump, secondly, numerous small clumps easily visible to the naked eye, and thirdly, extremely fine clumps, invisible to the naked eye but visible only with the hand lens. Whenever the absorption test was indicated to determine the true nature of the antibodies present the Barrett's (1941) modified technique was followed using boiled and phenolized guinea-pig kidney and ox cell suspensions as the absorbing antigens. Table I below shows the variety of heterophile antibody and the means to detect that by the absorption technique :—

TABLE I

Variety of heterophile antibodies	Treated with	
	Ox cells	Guinea-pig kidney
'Normal' ..	Not absorbed	Absorbed
Serum-sickness ..	Absorbed	
Glandular fever ..	"	Not " absorbed

Results

Three hundred random samples of Wassermann sera and 300 samples of sera received for Widal tests were submitted to Paul-Bunnell tests with the technique above described. The results as

expressed in the final dilution of serum are summarized in the following table:—

TABLE II

Serum dilution	WR sera	Widal sera
10	22	3
20	2	0
40	1	0
80	1	1
160	0	1
TOTAL ..	26	5

Two out of 26 Wassermann sera showed a titre of 1 in 40 and 1 in 80. These two sera, when submitted to the absorption technique, showed that the antibodies did not belong to the glandular fever type. Since 24 out of 26 sera were negative in a dilution of 1 in 80 by Paul-Bunnell test, that dilution was taken as the minimum diagnostic titre for the diagnosis of glandular fever, while a titre of 1 in 40 was considered as suggestive of that condition, requiring either an absorption test or a repetition of the Paul-Bunnell test on a second sample. This information was essential in view of the paucity of published data concerning the distribution of heterophile agglutinins in normal population and few reports that are available refer to Paul and Bunnell (1932), Stuart *et al.* (1934), Davidsohn (1937) and Barrett (1941) who have stressed the need of a preliminary study of the normal population, in the absence of any uniformity of technique. Besides normal sera, 300 Widal sera were tested with a view to detecting if any cases of pyrexia due to this disease were missed. The two Widal sera that gave positive results in a dilution of 1 in 80 and 1 in 160

had a typical course of enteric-like infection with all laboratory findings repeatedly negative. It was difficult to account for these findings in these 2 cases but the absorption test on these sera proved that the agglutinins were not of the glandular fever type. Even in normal sera small amounts of an antibody, indistinguishable from glandular fever antibody, may exist. Barrett (1941) examined 300 normal sera and demonstrated this in 5 of them, establishing the fact thereby that mere presence in a patient's serum of a sheep cell agglutinin which is absorbed by ox cells but not by guinea-pig kidney does not provide proof that the patient is suffering from glandular fever.

The number of samples of sera specifically sent for the diagnosis of glandular fever was 64, out of which 53 were received from the Royal Naval Hospital in Bombay and the rest from different hospitals. Fifty-three samples were collected from 44 cases in the same hospital, out of which only 12 cases were clinically diagnosed as glandular fever. Out of these 12, only in 7 cases, the laboratory confirmation by way of Paul-Bunnell tests was obtained. In the remaining 5 cases, Paul-Bunnell tests, when repeatedly done, remained negative. The remaining 32 cases in which glandular fever was initially suspected were finally labelled on clinical grounds as dengue, infectious hepatitis, tonsillitis, pharyngitis, scrub typhus, PUO and NYD.

Observations on the diagnosis of glandular fever

This disease chiefly attacks young children and adults, male patients preponderating. In

TABLE III
Summary of the laboratory and clinical findings in seven cases of glandular fever

Case number	Sex and age	Day of fever	Sore throat	Enlarged glands	Rash	Total WBC per c.mm.	Monocyte differential count, per cent	Paul-Bunnell test titre
I	Male, 24	5th	Present	Present	Nil	16,000	76	1 in 80
II	Male, 19	7th	Present	Present	Nil	16,000	83	1 in 640
		15th	Absent	"	"	8,600	60	1 in 80

VI	Male, 19	15th	Absent	Absent	Absent	19,800	82	1 in 160
		18th	1 in 160
VII	Male, 22	8th	Absent	Present	Absent	1 in 640

required further laboratory and clinical investigation. One of them was sent for sero-diagnosis of brucella infection by one of the hospitals. Later on a brucella organism was reported by blood culture from that case. The other case

the present series all the patients are adult males except one. In nearly all cases the history revealed some days of malaise before the onset of acute illness followed by a mild or severe sore throat. Faucial involvement was

present in 4 out of 7 patients and in all cases microscopic and bacteriological examination of throat swabs excluded infections with diphtheria, hæmolytic streptococci or organisms of Vincent's angina. The involvement of lymphatic glands was another characteristic feature in 6 out of 7 cases. The posterior cervical, axillary and inguinal glands were involved in turn and they were discrete, with a rubbery feel but not tender. The adenitis was accompanied by sharp pyrexia, the fever being irregular, ranging from 100°F. to 103°F. A fleeting erythematous rash was present in 2 out of 7 cases only. Paroxysmal cough and dysphagia when present indicated involvement of mediastinal group of glands. Slight enlargement of spleen was common. Jaundice occurred in 1 case only. All the patients made uneventful recoveries though one fatal case is recently recorded by Ziegler (1944). The blood changes are usually characteristic but they are transient. After a fleeting polymorphonuclear leukocytosis the count shows a characteristic increase in the number of mononuclear non-granular cells which vary from 40 to 90 per cent of the total leukocytes instead of the normal 20 per cent. The total leukocyte count is rarely more than 12,000 to 18,000. The red cells are not diminished in number. In this series, the number of mononuclear non-granular cells varied from 53 to 83 per cent while the leukocytosis was moderate varying from 8,000 to 20,000.

Discussion

Paul-Bunnell tests.—Paul and Bunnell examined 2,000 cases representing 76 clinical conditions including acute adenitis, tubercular, syphilitic adenitis and other diseases associated with glandular enlargement. In all these, either the reaction was negative or only feebly positive at a low titre. The heterophile antibody in the form of an agglutinin for sheep red cells is usually sufficiently strong to be diagnostic by the fourth day of the disease and it is present in high titre during the active phase. It may disappear within two weeks but is generally detectable in decreasing amounts for 4 to 5 months. Whatever may be the significance of the agglutinins for sheep erythrocytes, which are developed in the disease, demonstration of their presence in appreciable titre is still an essential factor in diagnosis. Attention is drawn to the following features:—

1. In cases seen by the 4th or 5th day, a diagnostic titre of agglutinins had already been reached (cases nos. 1 and 5).

2. Cases in which a titre of 1 in 40 or less on the 6th day of disease was noted showed a rise to 1 in 160 or more within 4 to 8 days (cases nos. 3 and 4). This showed the rapid rise which might occur and illustrates the necessity of repeated examinations for rise in titre but the fact that a rapid increase may occur in a short time probably renders this

observation invalid in the absence of serial daily determinations.

3. The titre once established may not last for a long time was shown in case no. 4. In the sample examined on 27th day of disease no agglutinins could be demonstrated.

4. The importance of the absorption tests with guinea-pig kidney extract and boiled ox erythrocyte suspension was well illustrated in cases nos. 1, 5 and 6, where the titres were not high or there were no opportunities of further examination of the samples. That the two sera in the Widal series did not possess any antibodies of the glandular fever type was proved by the absorption test alone. A reference has already been made to 5 cases of glandular fever diagnosed on clinical grounds but with repeated negative Paul-Bunnell tests. Cases of this type are on record where the heterophile agglutinins may be delayed as late as 10th week (Himsworth, 1940) or they may not develop at all throughout the course of the disease (Fuller, 1941). Shafar and Weir (1943) described an outbreak of glandular fever in Scotland affecting about 200 persons on which the Paul-Bunnell reaction was almost uniformly negative. Under these conditions it has to be stressed that a positive Paul-Bunnell test in the diagnostic titre and in the absence of serum-sickness confirms the diagnosis of glandular fever when taken in conjunction with the clinical findings, while a negative test does not necessarily exclude that condition. Low titre or border-line reactions require further confirmation by absorption tests.

Summary

1. To determine the level of heterophile antibodies in the local population 300 Wassermann sera were submitted to Paul-Bunnell tests, the technique of the test being fully described. The absorption test was carried out with Barrett's modification.

2. To find out if any cases of pyrexia due to glandular fever were missed, 300 Widal sera were similarly tested. Two of these sera were positive in a diagnostic titre of 1 in 80 or over but the absorption test showed that the antibodies were not of the glandular fever type.

3. Fifteen out of 64 sera, specifically received for the diagnosis of glandular fever, gave positive results with the Paul-Bunnell tests. They were derived from 7 cases; the laboratory and clinical findings of these are summarized.

4. The clinical diagnosis of glandular fever and the significance of positive and negative Paul-Bunnell test is discussed and the value of the absorption test in low titre reactions stressed.

My thanks are due to Surg. Capt. Vickery of the Royal Naval Hospital, Bombay, for permission to use clinical reports and to Surg. Lt. Allan and Surg. Lt. Pugh for their kind help.

STUDIES OF RINGWORM*

Part IV

INCIDENCE OF *TRICHOPHYTON GYPSEUM* IN INDIA

By L. M. GHOSH, M.D. (Cal.), D.T.M. (L'pool)
 N. C. DEY, B.Sc., M.B. (Cal.)

and

D. PANJA, M.B. (Cal.)

School of Tropical Medicine, Calcutta

(Financed by the Indian Research Fund Association)

Trichophyton gypseum Bodin 1902 or any of its many variants has not been recorded in India as yet. It is the cause of the small-spored ectothrix trichophytosis in man. Being of animal origin it produces more inflammatory reactions than other ringworm fungi.

In children.—It causes the ringworm of the scalp (*Tinea capitis*) often producing the condition called the 'kerion' in which the affected patches are acutely inflamed and raised to a boggy swelling; the hair follicles are gaping wide and contain pus, the hairs become loose and easily come out.

In adults.—Besides causing ringworm of the scalp it affects the secondary sex hairs causing sycosis barbæ (*Tinea*) in the beard region and pustular folliculitis in the pubic region. It also affects the lanugo hair, the glabrous skin and the nails. Similar inflammatory reaction takes place when it affects the hair follicles of the beard and pubic regions and also the lanugo hairs. The affections of the glabrous skin and the nails resemble ordinary ringworm lesions.

Materials

The present observations are based on the following cases :—

A. Hair infection (ectothrix):

Beard and moustache	.. 2 cases
Generalized infection	.. 1 case
Scalp (kerion)	.. 1 case

Some samples of hair from cases of ringworm of the scalp in the Gurkha troops.

B. Skin infection :

Interdigital	.. 2 cases
Nail infection	.. 1 case

Method of Study

In all cases the fungus was first detected by microscopic examination of the hair, nails or scales from the lesions, and the species was then identified by cultural methods.

Microscopic examination. (a) *Hair.*—The hair from the scalp or beard areas showed infection with *Ectothrix trichophyton*. The spores were small about 3 microns in diameter situated outside the hair arranged in groups or in a linear way. The mycelia showed beaded appearance due to the formation of arthrospores (see figures 3 and 4, plate VI).

(b) *Scales and nails.*—In the skin and in the nails the fungus showed segmented mycelia with occasional branching.

Mycology

Primary culture.—Primary cultures were put up on Sabouraud's proof medium and on Sabouraud's proof medium containing gentian violet (1 : 400,000) to inhibit the growth of the pyogenic cocci.

In Sabouraud's media the growth appeared usually on the third day after inoculation. The character of the growth was granular, the centre was slightly brown or yellow in colour and the margin was white. The surface was powdery, yellowish brown in colour. The powder was coarse and more thinly spread at the periphery. After some days the centre was often raised forming a central boss with concentric ring formation at the periphery (see figure 5a, plate VI). Occasionally there were furrows radiating from the centre. The growth was fairly rapid and covered a surface area of 5 cm. in diameter in two weeks.

In the media containing gentian violet the appearance of the growth was delayed to the fourth or fifth day after inoculation and its further progress was necessarily slow.

Subcultures.—(a) Sabouraud's proof medium—the growth maintained its rapidity and reached 6 cm. in diameter in 2 weeks and about 10 cm. in 6 weeks. Two types of growth were observed : (i) granular and (ii) fluffy. The granular type was usually seen in recently isolated cultures (see figure 5b, plate VI) while the fluffy type was found in comparatively old cultures (see figure 5c, plate VI). In the granular type characteristic end organs were found in good numbers, while in the fluffy type the end organs were few and rudimentary in character. In some subcultures both the types of growth were often mixed up; some portion was granular and some portion fluffy or velvety.

(b) Sabouraud's medium of conservation—formation of a central crater in some cases.

(c) Glucose agar—character of growth was same as in Sabouraud's medium.

*Read at the Indian Science Congress held in January 1947 at Delhi.

(d) Cereals, wheat and barley—growth was brown and granular in character.

Reproductive forms (end organs)—wheat-starch water was used as a nutrient solution for the study of the end organs and hanging drop preparations were made with it in wetted slides.

(a) Macroconidia or fuseaux were found in abundance in a recently isolated granular culture. These were short, stumpy and clavate and varied in size from 40 to 50 microns \times 7 to 8 microns and contained 3 to 4 cells (see figure 6a, plate VI). (b) The aleuriospores of conidia were profuse, round and small in size from 2.5 to 2.8 microns in diameter and formed clusters known as grappes or thyrsi (see figure 6a, plate VI). (c) Chlamydospores of intercalary type were also present. (d) The spirals were few at first but their number increased with the age of the culture. These were coiled closely or loosely according to the moisture contents of the media, the coils loosening with the drying up of the media. The spirals were abundant round the spore clusters known as grappes or thyrsi and formed the 'sterile perithecia' of Langeron and Milochevitch (see figures 6a and 6b, plate VI).

Old cultures which were on the way to pleomorphic changes showed few fuseaux but clubbed-end mycelia and aleuriospores in groups were present.

Pleomorphism.—The pleomorphic changes were relatively quicker in this than in other trichophyta, taking about 6 weeks to show the changes on Sabouraud's proof medium. In Langeron and Milochevitch's cereal and starch-peptone media the pleomorphic changes were slower. On Sabouraud's proof media the changes started from the central boss which became white and covered with velvety down and gradually extended to the periphery. Sectorial pleomorphic forms were also noticed in some cases, in which some portion of the growth was granular and the rest downy. When completely pleomorphic the mycelia were sterile and did not contain any spores.

Animal inoculation.—A portion of the back of a guinea-pig was shaved and an emulsion of the fungus (from the granular type of growth) with normal saline was rubbed on the part. Evidence of infection was found on the tenth day and microscopic examination of the hair from the lesion gave positive result. The fungus could be easily recovered from the lesion. The experimental lesions were found to be extending gradually all around the original site (see figure 7, plate VI).

Repeated attempts failed to produce the lesions when guinea-pigs were inoculated with the downy pleomorphic growth—thus showing that pleomorphism is the degenerative form of the growth.

Clinical Types

The following clinical types were observed:—

1. Beard and moustache area—2 cases. In both the cases the infection was in patches with

intervening normal areas. The patches were raised, inflamed and painful. The affected hair follicles were pustular. In the textbooks moustache area is said to be affected rarely but in both the cases of this series the moustache areas were involved (see figure 1, plate VI).

2. Scalp—(a) Kerion condition in a child (see figure 2, plate VI).

(b) Ringworm of the scalp in Gurkha troops.

3. Generalized infection—1 case. Generalized infection of the hair causing pustular folliculitis in several small patches affecting the beard area, pubic region and both the upper and lower extremities. The patches were raised, inflamed and painful; the infected hairs were loose (not brittle) and the hair follicles contained pus.

4. Skin—Interdigital spaces in the hands simulating ringworm.

5. Nail—Similar to that of an ordinary ringworm infection.

Discussion

In the textbooks many variants of *T. gypsum* have been mentioned such as *T. asteroides*, *T. radiolatum*, *T. granulosum*, *T. lacticolor*, *T. farinulentum* and *T. persicolor*, etc. It is well known that *T. gypsum* is very unstable and undergoes pleomorphic changes soon after isolation. According to the degree of pleomorphism the character of the growth changes from granular to fluffy or velvety type and the number and character of the end organs also undergo changes. The characteristic fuseaux very soon disappear and are replaced by the clubbed-end mycelia which also disappear on further degeneration. The spirals change from closed to open wind according to the moisture content of the media. In the fully pleomorphic stage the growth is white, fluffy and the mycelia sterile bearing only a few rudimentary aleuriospores.

Based on the above findings it can be safely concluded that the many variants mentioned in the textbooks are but different forms of the same mother species in the various stages of its degeneration.

It is proposed therefore to include all the variants mentioned into one species *T. gypsum* Bodin 1902.

Summary

1. Incidence of *Trichophyton gypsum* is recorded for the first time in India.

2. The fungus was isolated from the hair, skin and nails.

3. In all the cases the recently isolated culture had the same character of growth and produced the same end organs.

4. As the culture grew old, various pleomorphic or degenerative changes occurred and

with the degree of pleomorphism the character of the growth changed from granular to fluffy or velvety type.

5. The number and character of the end organs changed with the degree of pleomorphism resembling one of the many variants mentioned in the textbooks.

6. It is proposed to include all the variants into the mother species *T. gypsum* Bodin 1902.

Acknowledgment

We express our grateful thanks to Major C. D. Calnan, R.A.M.C., who sent us some samples of hair from cases of ringworm of the scalp in the Gurkha troops for identification.

A Mirror of Hospital Practice

A CASE OF TRAUMATIC IRIDODIALYSIS TREATED BY OPERATION

By E. J. SOMERSET

CAPTAIN, I.M.S.

Professor of Ophthalmology, Medical College, Calcutta

THE opportunity of operating upon a case of extensive iridodialysis rarely presents itself and it is therefore thought that a report on a case may be of interest. The iridodialysis in most cases is too small to require surgical repair but a larger one may give rise to diplopia and diminished vision. The operation may also be performed for cosmetic reasons.

Spaeth (1939) describes the operation and various modifications by Key (1932), Jameson (1909), and Wheeler (1934).

Case report

P. R., age 34, male, while repairing a telephone pole, was suddenly struck in the left eye by one of the wire supports. The wire had a diameter of about $\frac{1}{2}$ inch and it was the side of the wire, not the sharp end which struck him. He was treated in the local hospital and about three weeks later was admitted to the Eye Infirmary, Medical College Hospital, Calcutta.

On examination.—Left vision = 6/24. There was no congestion and the eye was quiet. Cornea normal. Anterior chamber deep. The pupil was irregular but there were no synechia or K.P. A large iridodialysis from 1 o'clock to 5 o'clock was seen (see figure 1). Some traumatic lens opacity was apparent. Tension was normal. Vitreous and retina appeared normal.

Right eye vision = 6/6 normal.

Operation.—On 18th March, 1945, the eye was cocaineized and the upper division of the

facial nerve was infiltrated with novocaine 2 per cent. A small conjunctival flap was dissected

up from 2 to 4 o'clock (see figure 2). A keratome incision was made at 3 o'clock in the

selera about 1.5 mm. from the apparent limbus (see figure 3). Iris forceps were introduced and the lower half of the peripheral border of the

iris dialysis was grasped and gently pulled into the lips of the wound (see figure 4). The upper half of the peripheral border of the dialysis was

then treated in a similar manner. This resulted in the complete reposition of the iris except for a very small 'button hole' at 1 o'clock (see

figure 5) which was left as complete reposition would have necessitated extension of the incision upwards. The iris was drawn into the wound

so that its edge was included in the lips of the wound but not so far as to prolapse through the wound. The conjunctival flap was sutured with

one stitch and one drop of guttae atropine sulphate 1 per cent instilled.

Progress was uneventful; the eye healed rapidly and was white in 8 days. The tension remained normal. Subsequently the pupil was seen to be slightly dilated and only reacted to light on the nasal side. Vision improved to 6/18.

Comment

The operation proved to be very easy and no reaction was observed. No iris stitch was found to be necessary, the edge of the iris adhering between the lips of the keratome incision most satisfactorily. It would seem that stitching the iris to the sclera is not desirable as the risk of iritis would be much greater.

Summary

A case of traumatic iridodialysis and its operative repair is described.

A PRESUMPTIVE CASE OF ERYTHRO-BLASTOSIS FOETALIS DUE TO Rh INCOMPATIBILITY

By S. D. S. GREVAL

LIEUTENANT-COLONEL, I.M.S.

Imperial Serologist

A. B. ROY CHOWDHURY, M.B.

Second Assistant

and

B. BANERJI, M.B.

Assistant Research Worker, I. R. F. A.

(From the Imperial Serologist's Laboratory, Calcutta. Partly financed by the Indian Research Fund Association)

ON 9th December, 1946, two samples of blood, (i) in citrated saline and (ii) in a dry tube from a mother who had given birth to a baby three days before, the baby developing jaundice on the second day of life, were received from Eden Hospital, Calcutta. Neither the baby's blood nor the father's blood was received.

Serological findings.—The mother was a subject B and Rh— (by animal and human sera).

The mother's serum agglutinated red blood cells (rbc hereafter) of 10 Rh positive group B and 7 Rh positive group O subjects so far tested

but failed to agglutinate the rbc of a Rh— group B subject. The tests were performed both on slides and in test tubes. Hæmagglutination appeared rather late (in about 45 minutes) on slide but was not poor. The reaction in the tube in 1 hour was satisfactory. The titre was low. The hæmagglutination improved on increasing the quantity of serum.

The mother's serum contained both the anti-Rho and anti-Rh' bodies. As known Rh" rbc were not available at the time the presence or absence of anti-Rh" body could not be determined. The serum may be called anti-Rho' or anti-Rh₁.

The mother.—Mrs. P. R. V., Parsee, aged 34 years, married 3 years, twice pregnant. No history of blood transfusion. Wassermann reaction negative.

First child, premature (8th month), died on the 4th day with jaundice (probably not caused by Rh incompatibility).

Second child, present baby.

The baby.—Full term. Jaundice noticed on the 2nd day, deepened and killed the baby on the 5th day.

Blood from the baby never became available for testing. That a baby is born apparently normal and develops jaundice later is known and appears to be the usual sequence of events. During intra-uterine life the mother disposes of the products of destruction of rbc of the fetus. They accumulate after birth only (Hallwright, 1946).

The family.—Contact with the father could not be made. As there is no child alive the parents are anxious to save the next baby. The mother has been told that (i) a baby not subject to the disease is possible and that (ii) attempts can be made to save the next baby by making arrangements for blood transfusion, etc., in advance. An account of the arrangement has been given previously (Greval, Roy Chowdhury and Banerji, 1946b). A slightly different plan has been given recently (Cappell, 1946). According to this plan (i) the serum from the mother is examined monthly, after the 6th month of pregnancy, for the rising titre of the anti-Rh bodies, (ii) Caesarean section is considered when the father is homozygous Rh positive, and (iii) the colour of the umbilical cord and of the plasma of the cord blood is examined immediately on birth and if found icteric (in an Rh+ baby) a blood transfusion (of a suitable blood) is given without waiting for the appearance of the clinical symptoms of erythroblastosis foetalis.

Presumption of sensitization of a mother.—Even without the use of an anti-Rh serum (human or animal) the presumption of sensitization of a mother arises when her serum gives anomalous group reactions. Such reactions given by the sera of pregnant women and quite unconnected with Rh, however, are known (Dockeray and Sachs, 1944). The writers

recently reported the case of an expectant mother O whose serum agglutinated 41 samples of rbc O, including 2 ORh— samples. Although she was Rh— the anomalous intra-group reaction was not due to an anti-Rh agglutinin (Greval, Roy Chowdhury and Banerji, 1946a). In the present case, however, the mother's serum contained an anti-Rh body.

The case remains presumptive inasmuch as the child's blood was not available.

This is the second case of presumptive erythroblastosis reported by the writers. The first case was reported last year (Greval, Roy Chowdhury and Banerji, *loc. cit.*). So far 2 cases have been detected in less than 12 months.

The serum is not suitable as a testing serum. Its titre is low. Conglutination does not raise the titre.

The writers are indebted to Major G. B. W. Fisher, I.M.S., and Dr. Miss A. Sen for sending the blood.

Therapeutic Notes

NOTES ON SOME REMEDIES

VI. SULPHONAMIDES

II

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
 T.D.D. (Wales), F.S.M.F.

Professor of Tropical Medicine, School of Tropical
 Medicine, Calcutta

General considerations

Good and sometimes spectacular results with sulphonamides are obtained usually in the acute infections, but in the main these drugs do little good in chronic conditions. For example, in acute gonorrhoea this therapy works wonders in 4 or 5 days, whereas in chronic gonorrhoeal arthritis little or no response can be expected. Best results are obtained if they are given early when the infecting organisms are still small in number: in pneumonia, specially, treatment should be begun before the development of the classical signs. Under-dosage is still far too frequent; if there is a real indication, they

should be used boldly in adequate amount without the physician's mind being fixed on the rare event of agranulocytosis. On the other hand they are not to be given indiscriminately in every low grade infection which heals up spontaneously. The importance of rapid raising of blood concentration has already been stressed. In severe infections this should be ascertained during the first two or three days or even earlier if possible; this may go far to explain failure and to suggest the next move in therapy. Likewise, the course of diseases like meningitis and septicæmia is best controlled by bacteriological examination. But if such examinations are not possible the drugs can still be used with reasonable safety and success, provided that the instructions here outlined are applied with common sense. In this connection it should be noted that the sulphonamides can inhibit bacterial growth in pathological fluids, so in sending a specimen, the bacteriologist should be informed that the patient is receiving these drugs, so that he may use the special culture medium required. Relapses can be treated with renewal of the drugs, but before doing so a white blood cell count should be made.

Ancillary treatment is as important as in any other therapy. Sulphonamides may not be a substitute for surgery and operative treatment should never be unduly delayed because they have been used. Virus infections, with the possible exceptions of trachoma and lymphogranuloma inguinale, do not respond to these drugs, but there is evidence that they have a definite place in the treatment of secondary bacterial conditions. Finally, there are no special contraindications to their use except severe hepatitis and advanced renal disease, especially with nitrogen retention. Some caution is required in pregnant and lactating women as these drugs are slightly excreted in milk and they pass through the placenta into the foetal circulation, though they need not be withheld for that reason. Racial susceptibility is worth remembering.

Therapeutic uses

In this section only some of the essential points are given and it has not been possible to give greater details within the limited space.

1. *Hæmolytic streptococcal infections*, e.g. cellulitis, erysipelas, septicæmia, etc.

In *septicæmia* sulphanilamide is very effective. If the response is not satisfactory, small blood transfusions (200 to 300 c.c.) are indicated. Any septic focus will require adequate treatment, but abscesses should not be incised until fully ripened, and care must be taken not to open up fresh channels of infection. Excellent results have been obtained in *erysipelas*; the spread of the lesion is stopped in 48 hours and the fever subsides in 3 to 4 days. Treatment should be continued with reduced dosage for a further period of seven days to prevent relapse. In *puerperal sepsis* sulphonamides have greatly reduced the mortality, the best results being

obtained with high blood concentrations. Quick relief follows in *acute otitis media* and *mastoiditis* both of which should be treated as severe infections, but the symptoms are liable to be masked and careful watch must be kept on the drum-head and mastoid bone as surgical intervention may be necessary. Treatment should be continued for a week to prevent relapse. If purulent discharge sets in, the infection rapidly becomes a mixed one of streptococci and staphylococci, when sulphathiazole or sulphadiazine should be preferred. Careful local treatment is necessary.

The great majority of non-hæmolytic streptococci are insensitive to sulphonamides.

2. *Staphylococcal infections*.—In severe cases sulphonamides should not be relied on if penicillin is available, particularly in acute osteomyelitis, cavernous sinus thrombosis, severe carbuncle, septicæmia and staphylococcal pneumonia and meningitis. In its absence sulphathiazole is the drug of choice. *Septicæmia* due to this cause is a serious condition with a high mortality. Give maximal or still higher dosage, even at the risk of toxic reactions. To avoid relapse or recrudescence, treatment should not be interrupted unless a pronounced clinical improvement or a dangerous toxic reaction occurs. The minimal dose should be 12 to 18 gm. a day (2 or 3 tablets two hourly) for three days, followed by 2 gm. four hourly for a further four days. If necessary the treatment should be continued for a longer period. Blood cultures are helpful as a guide to dosage and the length of the course. A colony of 20 or over per c.c.m. is a bad prognostic sign. A co-existing focal lesion such as abscess or osteomyelitis is of good omen. Small repeated blood transfusions are of great value.

Both in streptococcal and staphylococcal septicæmia full doses of sulphonamide and penicillin would seem the most promising combination, since some strains of streptococcus and staphylococcus are resistant to one or other of the drugs.

Sulphathiazole given early in *acute osteomyelitis* not only controls the systemic infection but also limits the bone infection, but it has to be combined with surgery when there is already bone damage and abscess formation. Treatment should not be stopped after the first few days when the disease may appear to be under control. The affected part should be immobilized. The cause of death is usually staphylococcal septicæmia and the patient should be treated as a case of severe infection. In *impetigo contagiosa* the drug is applied as a 5 per cent cream or paste twice in the day and night after removing the crusts and scabs. The condition gets almost cured in 5 or 6 days, but quicker results have been reported with 15 per cent suspension of microcrystalline sulphathiazole. Treatment should not be continued longer than 5 days, as patients are liable to develop hypersensitivity.

3. *Meningococcal infections* (cerebrospinal fever).—Chemotherapy has greatly reduced the mortality from this disease. It is vital to secure adequate blood concentration at the earliest possible moment and to maintain it for several days. Another point that is likely to be overlooked is the need for giving sufficient fluid to comatose patients. The initial dose or doses, except in mild cases, should be given intravenously as soon as lumbar puncture has shown the fluid to be turbid and without waiting for bacteriological examination. The fluid may not always be purulent, but the presence of even one or two polymorphonuclear cells should arouse suspicion. The dosage is higher than usual, no infant should be given less than 3 gm. daily during the first two days of treatment, for adults during this period 12 gm. daily is an appropriate dose and for children an intermediate amount. Intravenous (or intramuscular) injections may have to be repeated if the clinical condition does not improve within 2 or 3 days. When repeating lumbar puncture only a small quantity of fluid should be removed (5 c.c.) to prevent loss of sulphonamide. With clinical improvement the dose is reduced but the drug should be continued for about 10 days.

Meningitis due to *pneumococci*, *staphylococci* and *H. influenzae*, etc., is relatively resistant to sulphonamide treatment. In most cases the infection is secondary to a primary focus elsewhere in the body such as pneumonia, otitis and sinusitis. Examination of the spinal fluid should be made at frequent intervals so that relapse which is much more common in these infections may be detected at the earliest stage and appropriately treated with renewal of high dosage. The drug should be continued for at least a week after the temperature has subsided and for a longer period in *H. influenzae* infection which is specially liable to relapse. Remarkably good results have been obtained by combined sulphonamide and penicillin therapy in pneumococcal meningitis in which the case mortality before the advent of chemotherapy was a little short of 100 per cent. The same combination should be adopted for all these types of meningitis, although *H. influenzae* are relatively more resistant to penicillin.

4. *Pneumonia*.—In pneumococcal infection temperature usually comes down within 48 hours, but the treatment should be continued for 5 days more. Resolution occurs rather slowly and physical signs may persist for as long as a fortnight, but the drugs should not be given longer than 7 days. Age is an important factor in prognosis, and in the aged sulphonamides are not nearly so effective as earlier in life. Parenteral injections should be given in severely toxic patients or where the clinical response is poor. In some cases the drug has no effect when penicillin is indicated.

Adjuvants like oxygen, good nursing, etc., must not be forgotten.

In an average case of pneumonia, there is little to choose between the sulphonamides and penicillin so far as the end result is concerned, but there is a small percentage of patients over 40 for whom penicillin represents a definite advance on the sulphonamides. Generally the indications for its use are extensive pulmonary involvement, severe cyanosis and dyspnoea, heavy bacteraemia and lack of leucocytosis.

Pneumonia due to *streptococcus* or *Friedlander's bacillus* responds well to sulphonamides, although not so dramatically as in the pneumococcal disease. In *staphylococcal* pneumonia which is a very fatal disease penicillin is the drug of choice. *Bronchopneumonia* is caused by a wide variety of agents, against some of which sulphonamides may fail, but the difference in response seems to be more apparent at the extremes of life when the resistance to infection is poor. They are of value in *influenzal* pneumonia, provided the viral infection itself is not too severe; a leucocytosis favours the chance of a good response.

5. *Intestinal infections*.—Sulphonamide therapy has been strikingly successful in *bacillary dysentery*. In severe *Shiga* infections, the clinical response to sulphaguanidine is remarkable—abdominal pain and tenesmus are relieved in 1 to 2 days and the number of stools reduced to normal in a few days. Blood rapidly disappears although mucus persists for some time. Doses of 3 gm. four times a day for three days and then two or three times a day for four days are effective in all but the most severe infections in which the unit dose may be increased to 5 gm. Best results are obtained if treatment is started in 24 to 36 hours of the onset. In fulminating cases 50,000 to 100,000 units of concentrated anti-dysenteric serum (*Shiga*) should be given intravenously to combat the toxæmia. *Flexner* infections also respond very well, doses of 3 gm. being usually sufficient. Convalescent carriers are common among untreated patients, and these together with symptomless carriers can usually be cured by a course of sulphaguanidine. *Sonne* dysentery is rather resistant but it is a mild infection and the treatment is that of a convalescent carrier. Succinyl sulphathiazole (sulphasuccinyl) is reported to be equally effective and may be given in daily 10 gm. dosage, divided into five doses, but there has not been enough experience with it owing to short supply.

Although sulphaguanidine as a rule produces no toxic complications, large doses such as 24 gm. a day as originally used may result in high concentration in the body and if the drug is continued for more than 8 days, toxic symptoms become common. Succinyl sulphathiazole on the other hand is so poorly absorbed that it seems to be free from this danger.

These two drugs have been introduced on the hypothesis that, being poorly absorbed, they produce a higher concentration in the faeces and

hence are more effective than drugs which are well absorbed. If this hypothesis is correct, then succinyl sulphathiazole should be the best drug, but so far this has not been the case. Paulley (1942) suggested that it is not the concentration of the drug in the intestinal contents but the concentration in the blood which is the important factor. It is argued that bacillary dysentery is a systemic disease with focal intestinal manifestations and treatment should be more effective when the absorbable drugs such as sulphadiazine or sulphathiazole are used. This seems to be borne out by the fact that these drugs have given as good, or even better results, presumably because, besides having some local action, they are in a better position to act on the organisms lying in the mucosa. Reports are however conflicting and, according to our present knowledge, the following recommendations may be made. In severe cases sulphaguanidine should be given; in the dosage now employed it hardly ever has unpleasant side-effects and it is not advisable to give drugs which are toxic and easily liable to crystallize out in the urine of a dehydrated patient with oliguria. But as it is rather slowly absorbed it may be preceded by sulphathiazole during the first 24 hours. In other types of the disease, both forms of sulphonamides can be used, the dose of sulphadiazine or sulphathiazole being 2 to 4 gm. followed by 1 gm. 4 hourly, and later 6 hourly. All these drugs are not infallible and a change of drug in unresponsive cases may be an advantage. There is also some evidence that a combination of the two forms of drugs may be more desirable than either type alone in the acute phase of the disease. Succinyl sulphathiazole should be reserved for the treatment of Sonne dysentery and dysentery carriers who become bacteriologically negative after a course of 10 gm. a day for 5 days. It is also used in the pre- and post-operative stage of intestinal surgery owing to its marked property of reducing *B. coli* in the bowel—a property which is more noticeable with phthalyl sulphathiazole.

A few practical points may here be mentioned. Purgatives, high enemas and colon irrigations are contra-indicated. Fluid intake must be sufficient and, if necessary, glucose and saline injections are given intravenously. Sulphonamides should not be started in a dehydrated patient until steps have been taken towards restoration and maintenance of normal hydration. Lastly it should be noted that the dramatic relief of symptoms does not imply healing of the intestinal lesions; this usually takes some time and the convalescence should not be hurried, or there may be relapse. If possible, sigmoidoscopy and stool cultures should be made before a patient is declared as cured.

In *chronic bacillary dysentery and ulcerative colitis* reports are as yet inconclusive. In a few moderately ill patients sulphaguanidine has given complete remission of symptoms but

severe infections are unaffected. Full doses should be given, and it is often necessary to repeat the course. Where oral therapy fails, the use of retention enemas has been advocated, containing 7 to 10 gm. of sulphaguanidine or succinyl sulphathiazole in 7 ounces of water or mucilage. Such enemas can be retained from 6 to 8 hours, and to assist this, phenobarbitone or morphine is given as a bowel sedative.

Penicillin and sulphasuccinyl have given very promising results in *chronic amoebic dysentery* which has resisted the usual courses of treatment. An initial dose of 100,000 units of penicillin intramuscularly is given, followed by 33,000 units every three hours until two million units have been given. At the same time sulphasuccinyl is given until a total of 80 gm. has been taken. This course does not eradicate the amoebic infection but can deal with the secondary pyogenic organisms that invade the ulcers in the intestine and thus bring about conditions that permit a favourable response to anti-amoebic drugs. In the absence of sulphasuccinyl, sulphaguanidine may be used.

Sulphonamide therapy is also of value in non-specific colitis and in some cases of sprue along with liver injections or folic acid therapy. Chaudhuri and Rai Chaudhuri (1944) found sulphaguanidine very efficacious in controlling the diarrhoea.

In *cholera*, sulphaguanidine has already given favourable results, but trials are still continuing. Huang (1944) obtained rapid amelioration of symptoms with an initial dose of 3 gm. followed by 1 gm. every two hours for six hours and then 1 gm. four hourly for 1 to 2 days. In India the report of the Scientific Advisory Board (1945) records good results with a different method of treatment; sulphaguanidine was given in 3 gm. doses every four hours for 3 days, and then twice a day for 3 days. Such results are not obtained when treatment is started late. In any case usual steps should be taken to combat the dehydration and depletion of salts and colloids.

Finally it should be remembered that certain intestinal organisms synthesize vitamins and that sulphaguanidine and succinyl sulphathiazole given over long periods can reduce the natural flora of the bowel and thus inhibit the synthesis of many factors essential to the host, e.g. thiamine, members of B₂-complex such as folic acid, riboflavin, nicotinic acid, etc. Further a severe intestinal infection such as bacillary dysentery may in itself precipitate a deficiency state. It is therefore wise to attend to the vitamin B state of the patient when employing 'chemotherapy within the bowel'.

HOWARDS' QUININE

SALTS & TABLETS

Famous for over 100 years

Manufactured by

HOWARDS & SONS LTD. (Estd. 1797), ILFORD, LONDON

VIROL

and the proper nutrition of children

For more than forty years doctors have been observing what happens to children when they are given Virol in addition to their ordinary meals. In Hospitals, Welfare Centres and in private practice they have seen over and over again how quickly the growing body responds to Virol and how lasting is the improvement in growth, health and energy.

Virol is a concentrated and very

palatable food prepared from Malt Extract, specially refined Animal Fats, Eggs, Sugars (including Glucose), and Orange Juice, with added Mineral Salts and Vitamins. Virol is designed to provide, in carefully balanced proportions, those essential food factors (not vitamins alone, but also many other just as important, including iron, calcium, phosphates, etc.) which are most likely to be deficient in the rest of the diet.

Agents for India :

WATSON 'MX-2' X-RAY APPARATUS

The portable with the big performance

Compact and easily dismantled, Type MX-2 has the power for a wide range of radiographic procedures.

The rating is 80 kVp. at 15 mA; it has a generous screening rating, mains compensator, kilovoltage and mA controls and a 12 second timeswitch.

Type "MX-2" was adopted as the standard portable by the Army Medical Services and is particularly well suited to strenuous use in remote regions, the shockproof tube head being sturdy and immune to atmospheric conditions.

Delivery can at present be made from stock; write for literature to Watson & Sons, manufacturers of the officially adopted apparatus for Mass Miniature Radiography.

WATSON & SONS (ELECTRO-MEDICAL) LTD.

FEBRUARY

Rh BLOOD TYPES AND Hr

NOTHING in the immunological constitution of human red blood cells has grown so luxuriantly in such a short time as the details of the Rh antigens (Rh 'factor', a hæmagglutinin, an antigen contained in the red blood cells). Six years ago there was one *antigen*, Rh, and two *characters*, (i) Rh positive, Rh, dominant and (ii) Rh negative, rh, recessive. To-day there are three antigens and eight types. In addition, there is the Hr antigen (Hr 'factor').

The use of the indeterminate term 'factor' for the definite terms 'antigen' (in immunology) and 'character' (in genetics) has not contributed to the comprehensibility of the situation.

Another difficulty is the departure from the usual method of describing the basis of characters in genetics: The genes carrying the characters are composite, not single. One, two or three antigens (physical bases of characters) may occur together at the locus of a gene on the chromosome and are inherited together by the offspring.

Yet another difficulty arises in grasping the fact that the recessive character, responsible for the Rh negative state, is not really non-existent somatically as the character t (d would be better) is non-existent *vis-à-vis* T, in the genetics of the edible pea in Mendelism. With appropriate reagents both Rh and rh can be detected (Cappell, 1946).

What applies to the negative character rh applies to the positive characters with greater justification: No character in the genetics of Rh is recessive.

Once these difficulties are recognized and thus overcome the combinations of the antigens responsible for the types, as given in the scheme of the discoverer of the Rh antigen, are easy to follow. Additions made to the scheme by other workers are not necessary.

Rh types made easy.—The antigens are only three in number (Wiener, 1946a): Rh₀, Rh' and Rh". They occur singly or in combination thus:

	Antigen 1	Antigen 2	Antigen 3	Type as named
I	Rh ₀			rh ₀
II	Rh ₀	Rh'		Rh ₁
III	Rh ₀		Rh"	Rh ₂
IV	Rh ₀	Rh'	Rh"	Rh ₁ Rh ₂
V	..	Rh'		Rh'
VI	..		Rh"	Rh"
VII	..	Rh'	Rh"	Rh'Rh"
VIII	rh (Rh negative)

The types are the allelic genes, simple or composite.

Some of the types are common, others rare.

All the types can be determined by three antisera: Anti-Rh₀, Anti-Rh' and Anti-Rh".

It will be seen that four of the types contain the antigen Rh₀ while only one of them is known as the type rh₀ (originally described as Rh₀ and now again changed into Rh₀, *vide infra*).

It will also be seen that four types are without the antigen Rh₀.

Very recently their describer (Wiener, 1946c) has renamed four types thus:

Type	rh ₀	is to be	Rh ₀
"	Rh'	"	rh'
"	Rh"	"	rh"
"	Rh'Rh"	"	rh'rh"

Moreover, all types denoted by small r (rh, rh', rh" and rh'rh") are to be called Rh negative.

The eight types now are:

Rh ₀	{	Rh positive	
Rh ₁		(They are detected as positive, without differentiation between the antigens, by an animal testing serum. They contain Rh ₀ .)	
Rh ₂			
Rh ₁ Rh ₂			
rh'	{	Rh negative	
rh"		(They are detected as negative, without differentiation between the antigens, by an animal testing serum. They do not contain Rh ₀ .)	
rh'rh"			
rh			

A recipient falling under any of the four negative types cannot be transfused with blood from a donor falling under the positive types, because of the antigen Rh₀. All such recipients should be transfused from a strictly Rh negative donor of the type rh.

The possibility of the antigens rh' and rh" sensitizing recipients not possessing them remains, although clinically only the antigen Rh₀ appears to be potent in this respect.

Hr made easy.—This antigen has been responsible for considerable confusion because of the same letters in its symbol. For the present it will be sufficient to assume that it is an antigen (a hæmagglutinin) like A, B or M, N, but unlike them, is linked to certain Rh types. It occurs only in four types: (i) rh, (ii) rh", (iii) Rh₀ and (iv) Rh₂ (Hallwright, 1946). The other four types are free from it and are therefore Hr negative.

The Hr positive type is detected by an anti-Hr serum obtained from an Rh positive mother who has given birth to a baby suffering from erythroblastosis foetalis.

Of Hr also three types are possible: Hr₀, Hr' and Hr" (Wiener, 1946a).

The St serum may be considered synonymous with anti-Hr serum.

The incompatibility of an Hr positive donor for an Hr negative recipient has not yet been

commented upon. Evidently such an incompatibility exists and provides the important anti-Hr serum. The use of a donor of the type rh as a universal donor, therefore, cannot be safe.

CDE system.—This is Fisher's system which postulates 3 characters in a composite gene at a locus (quoted by Race, 1946). It includes both Rh and Hr characters. A comparison with Wiener's system and reactions of the antigens concerned are given below.

The brackets in the last two columns include the reactions Fisher has predicted (Wiener, 1946b).

Designations of antisera

Fisher Wiener		Γ Rh'	II Rh''	Δ Rh ₀	γ Hr'Hr	η (Hr'')	δ (Hr ₀)
Genes							
Wiener	Fisher						
rh	cde	—	—	—	+	(+)	(+)
Rh'	Cde	+	—	—	—	(+)	(+)
Rh''	cdE	—	+	—	+	(—)	(+)
Rh ₀	cDe	—	—	+	+	(+)	(—)
Rh ₁	CDe	+	—	+	—	(+)	(—)
Rh ₂	cDE	—	+	+	+	(—)	(—)
Rh' (Rh'Rh'')	CdE	+	+	—	—	(—)	(+)
Rh ₁ (Rh,Rh ₂)	CDE	+	+	+	—	(—)	(—)

It will be seen that C, D and E correspond to Rh', Rh₀ and Rh'' respectively. The small letters are the alleles of the capital letters (not the hæmagglutinins, unlike the scheme of representation in blood groups).

One serious objection to the CDE system is that in it are introduced many letters and symbols but none of them has any relation to the symbol Rh.

The complexity of the Rh system is not necessarily of a higher order than that of ABO and MN systems. Had the system remained in the hands of serologists or biologists it would have settled down like the other systems which have their subdivisions and their anomalous reactions. Mathematicians into whose hands it has fallen intend imparting to it the mathematical precision. Such an accomplishment, however, is not possible in biology which is based on variation and defies precision attained through mathematical subtleties.

Types or subtypes?—Both terms are in use. Type would be preferable, in conformity with M and N types. One determines the Rh +/— state and then the type of the state (Rh₀, Rh₁, Rh₂ and Rh₁Rh₂ for the positive state and rh, rh' and rh'' for the negative state).

VENEREAL DISEASES NUMBER

(Reprinted from November 1946 issue of *I.M.G.*, p. 483)

It is proposed to publish a special number, in October next year, on venereal diseases in India. Original and special articles on their diagnosis, prevalence, complications and treatment will be welcome.

Contributions will be received up to July 1947 and placed before a special editorial committee.

It has been established gradually during the last 10 years or so that the venereal diseases do not thrive in India. Serious doubts have been cast on the previous estimates according to which 20 per cent of the population not showing any signs of syphilis consisted of latent cases of the disease. Such a state of things in India is impossible for a variety of reasons (*vide* this journal, vol. 81, 1946, nos. 6-7, p. 253). Contributions running counter to the old estimates need not therefore be held back in diffidence any longer.

Venereal diseases other than syphilis and gonorrhœa, some of them of special tropical interest, are very seldom discussed in the current medical literature in India. Recently they have been commented upon in this journal (vol. 81, 1946, no. 9, p. 365).

Medical News

TUBERCULOSIS HEALTH VISITORS' CLASS OPENED AT DELHI

'The Health Visitor is considered as the front-rank soldier in the war against tuberculosis. In relation to the clinic the health visitor is, or should be, its eyes and ears', observed Lieut.-General R. Hay, Chairman, Tuberculosis Association of India, opening the class of Tuberculosis Health Visitors in New Delhi Tuberculosis Clinic this morning.

He added: 'We all know the terrible nature and potentialities for havoc of this scourge—tuberculosis—which has been classed as India's public enemy No. 2. The figures available regarding morbidity and mortality reveal that tuberculosis takes a toll of half a million lives in India every year'.

It is estimated that India should have one clinic to every 50,000 urban population and one for every 100,000 rural population, making a total of 4,600 clinics. With a minimum of two health visitors per clinic 9,200 visitors would be required for tuberculosis work in the country. As against this minimum need India to-day has only a little more than 100 clinics and 100 health visitors.

Enumerating some of the duties of the health visitors, Lieut.-General Hay said that they have to visit the patients' home, look after their comfort and give the necessary instructions to the patients and their relatives regarding treatment. They have also to conduct propaganda through demonstrations and educate the public on the prevention, control and care of the disease.

Lieut.-General Hay felt confident that after their training for eight months in Delhi and Kasauli the health visitors would contribute to the alleviation of human suffering in the course of their future duties.

BRITISH COMMONWEALTH AND EMPIRE HEALTH AND TUBERCULOSIS CONFERENCE, 1947

A CONFERENCE on tuberculosis, arranged by the National Association for the Prevention of Tuberculosis of Great Britain, will be held in London on the 8th, 9th and 10th of July, 1947. The conference will deal with tuberculosis in all its aspects, but with special reference to the problem as affecting the British Commonwealth, and representatives from all the Dominions and Colonies have been invited.

The sessions will include discussions on tuberculosis in the British Commonwealth and the Colonial Tuberculosis Services; sanatorium design; after-care and rehabilitation; the psychology of tuberculosis; new discoveries in the prevention and treatment of the disease, and the National Health Service and its effect on tuberculosis schemes.

Plans are being made for overseas guests to see something of the anti-tuberculosis work for which Great Britain is famous, and will include visits to sanatoria, hospitals and clinics, and demonstrations of various kinds. The conference is open to both doctors and laymen, and fuller particulars can be obtained from the Secretary-General, National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock Square, London, W.C.1.

PENICILLIN FACTS AND RUMOURS

UNDER this heading the Council of Pharmacy and Chemistry of the American Medical Association has issued (*J. Amer. Med. Assoc.*, 1946, 131, 1423) a notice because of unwarranted fears in the minds of the public concerning the value of penicillin and other new remedies, created by recent articles in the lay Press. Physicians, states the notice, should be in a position to

give their patients the facts concerning penicillin and to allay any doubts or fears created by these publications. Briefly, the facts concerning the latest developments in penicillin therapy are as follows:

1. Commercial penicillin has consisted of varying mixtures of one or more of the five known fractions: F, G, X, K and dihydro F.

2. Penicillin K is apparently rapidly destroyed or eliminated in the body, and therapeutic levels are not achieved or maintained in the body fluids following ordinary doses.

3. Commercial penicillin now available is predominantly penicillin G, which is known to be effective, although some of the penicillin produced for a few months in 1945 may have had relatively less G and more K than previous or subsequent batches.

4. As far as facts are available, penicillins F and X are as active clinically as penicillin G. Further research will be necessary to define their usefulness with preciseness.

5. Since precise methods are not available for the routine determination of the quantities of each fraction in each batch of penicillin, the National Research Council has recommended increased dosage of penicillin as a safety precaution, particularly in the treatment of syphilis, in which the end result of therapy cannot be evaluated for a long time.

6. Although bacteria have been made resistant to penicillin in the test-tube development of clinical resistance has not become a problem. Such an eventuality may be prevented, in part, by giving adequate and not minimum doses of penicillin.

7. All penicillin and penicillin pharmaceuticals currently on the market have been examined and certified as to safety and efficacy by the United States Food and Drug Administration.

8. It is possible that natural or synthetic variations of the penicillin molecule will result in the development of a clinically better penicillin. None better than penicillin G is now available.

The presence of penicillin K (under British nomenclature penicillin IV) is also the subject of an annotation in the *Lancet* (1946, ii, 387). The note states that the finding that penicillin IV is less efficacious chemotherapeutically than the other penicillins is of considerable practical importance since commercial penicillin is a mixture of different penicillins with an undefined proportion of penicillin IV. The amounts of the different penicillins in the commercial products depend on the strain of mould used in production and on the composition of the culture medium. Strains used by manufacturers up to 1944 yielded predominantly penicillin II (G), but since 1944 a change has taken place in the commercial penicillin preparations, leading to a fall in their content of II (G) and a rise in IV. Strain Q176, now used by most manufacturers because it gives the highest yield, produces under certain conditions a considerable proportion of IV. During the purification of penicillin now carried out an impurity may be removed which exerts a synergistic effect on the treponemocidal action of penicillin.

DIAGNOSIS OF LIVER ABSCESS

MAJOR C. E. LUMSDEN reports the following instructive case in the *Journal of the Royal Army Medical Corps*, Vol. LXXXVII, No. 2, August 1946 (p. 76):—
'Pte. X, aged 35. Treated for amoebic dysentery in Iraq and pronounced cured. Over a year later in Iraq he developed upper abdominal pain. Examination revealed an epigastric mass, apparently solid. A routine examination of the stool on two occasions disclosed "no amoebic cysts". A clinical and radiological diagnosis of tumour of the stomach was agreed upon and laparotomy performed. This revealed a large "cancer of the stomach already adherent to the liver", regarded as inoperable by the surgeon. The case was transferred to base and reconsidered by a consultant surgeon. Laparotomy was repeated; mass "larger and now definitely inoperable". The patient was evacuated to India—a hopeless case. Patient was grossly emaciated

and the laparotomy wound beginning to break down from secondary cancerous invasion. He died shortly after admission to hospital in India. At autopsy, the "mass" was an amoebic abscess of the left lobe of the liver with inflammatory adhesion to the stomach wall; there was advanced active amoebic colitis; and the "secondaries of the abdominal wall" were nothing other than entamoebal lysis of the abdominal wound.

UNITED PROVINCES MEDICAL COUNCIL

MINUTES OF THE MEETING OF THE UNITED PROVINCES MEDICAL COUNCIL HELD IN ITS OFFICE AT LUCKNOW, ON FRIDAY AND SATURDAY, 15TH AND 16TH NOVEMBER, 1946, AT 11 A.M. AND 1-30 P.M., RESPECTIVELY.

BEFORE the business commenced the following resolution, moved from the Chair, was unanimously passed—all standing:

'The United Provinces Medical Council places on record its expression of deep sorrow at the sad demise of Rai Bahadur Dr. D. D. Pandya, M.B., (Camb.), and of appreciation of the valuable services rendered by him as a member of this Council since 1929, and directs the Registrar to convey a message of condolence to the members of the bereaved family.'

1. The minutes of the last meeting of the United Provinces Medical Council were confirmed.

2. Government notifications nominating Colonel N. Briggs, M.R.C.S., D.P.H., V.H.S., I.M.S., as President and Dr. (Miss) S. S. Naidu, M.B., and Dr. C. P. Mism, M.B., as members of this Council were read and recorded.

3. Considered—With reference to Medical Council resolution no. 7 (10) (a) of March 1946, the case against Dr. Syed Asad Ali, M.B., was considered and, after hearing him and his counsel, the Medical Council unanimously judged him guilty. In view of this practitioner's past military services and his extreme old age, the Council took a lenient view and unanimously decided that a warning only should be issued to him.

As regards the allegations made by this practitioner against the Registrar, the Council took a very serious view of the matter. Dr. Syed Asad Ali and his counsel were therefore recalled. Dr. Syed Asad Ali, however, withdrew the aforesaid allegations and apologized to the Registrar in the presence of the Council for having made such unwarranted and uncalled-for allegations.

4. The case against Dr. Har Datt Pant, M.B., was considered. Since the Council felt that the presence of Dr. Har Datt Pant was necessary, it was resolved that the hearing of the case be postponed. The Council for the practitioner was informed of the postponement.

5. Withdrawn.

6. The Registrar's explanations on the audit and inspection note (no. T/561) on the accounts of the United Provinces Medical Council for the year 1945-46 were approved and accepted.

7. The statement of income and expenditure of the Council for the year 1945-46 was considered and approved. The excess expenditure over the budgeted allotments under some heads of expenditure was sanctioned.

8. The budget estimates of the Council for the year 1947-48 and the revised budget for the year 1946-47 were passed unanimously.

9. The case against Dr. Man Mohan Prasad Hajela, L.S.M.F., was considered and after hearing the practitioner, it was unanimously decided that the explanation of this practitioner was satisfactory and that no case had been proved against him. The practitioner was thereupon informed accordingly.

10. The case against Dr. Mashkur Ahmad, M.B., B.S., was considered and, after hearing him and his counsel, the Council accepted his explanation as satisfactory and decided that no further action was necessary.

The following resolution was then passed:

'That the attention of the State Medical Faculty be drawn to the fact that the certificate forms need clarification. It should be made clear on the form

whether a certain statement made therein is on the personal knowledge of the certifying medical practitioner or is based on the statement of the compounder concerned.'

11. The case against Dr. Brij Bhushan Lal Dargar, L.C.P.S., was considered.

In view of the departmental action which has already been taken against this practitioner, the Council decided that no further action was called for.

12. The case against Dr. Sudhir Chandra Ghose, L.M.P., was considered and Dr. Ghose and his counsel were heard.

In view of the fact that his name has been erased by the Bihar Council, with which body this Council is on terms of reciprocity, it was unanimously decided that a similar action should be taken by this Council also.

13. Resolved that in view of the loss having occurred on war services, a duplicate copy of the registration certificate may be supplied to Dr. Lakhan Singh free of charge.

14. Resolved unanimously that Rai Bahadur Dr. B. N. Vyas should be re-elected to represent this Council on the Board of High School and Intermediate Education.

15. Resolved unanimously that Captain H. N. Shivapuri should represent this Council on the Council of Physical Culture.

16. Resolved that the L.M. Diploma granted by the National Maternity Hospital, Dublin, be recognized for registration in this province as an additional qualification.

17. Resolved that the L.M.P. (Orissa) qualification may now be recognized for registration in this province.

18, 19 and 20. (Please see proceedings of the second day's sitting.)

21. Resolved that the sitting members of the standing committee may continue during the year 1947 with Rai Bahadur Dr. Rameshwar Singh in the place of the late Rai Bahadur Dr. D. D. Pandya, M.B., (Camb.).

(Proceedings of the second day's sitting)

18. Resolved that this Council is in agreement with the proposal of the Medical Council of India of adding a third group to the proposed All-India Medical Register.

19. The question whether any further representation to Government was necessary now that Parts I and II of the United Provinces Indian Medicine Act (X of 1939) have been enforced was considered and the Council passed the following resolution:

'Now that the United Provinces Indian Medicine Act has come into force, the Medical Council desires to bring to the notice of the Provincial Government that the examinations and syllabus laid down for registered Vaid and Hakims do not provide adequate training to qualify them to issue the various certificates (Injury, Age, Birth, Death, Medical, Physical Fitness certificates, besides other certificates) which they are now empowered to do under the above Act. Medical certificates require a thorough knowledge of Medical Jurisprudence which is broadly based on the knowledge of Anatomy, Pathology, Medicine, Surgery, Chemistry and Toxicology in which this class of practitioners are not thoroughly trained. Some of these subjects are not taught at all.

It would not therefore be in the interest of the public, in fact it would be dangerous to, to authorize these practitioners to give evidence at Inquests and Courts of Law and to have privileges under the Excise Act.

20. Postponed.

21. (Please see the proceedings of the first day's sitting.)

22. The report of the Standing Committee, dated 14th November, 1946, was considered, and its recommendations were accepted with the exception of one item the consideration of which was postponed.

23. The report of the Sub-Committee, dated 23rd September, 1946, and the amendments proposed thereto, were considered, and the Council approved certain

amendments to be made to the United Provinces Medical Act and the rules and regulations thereunder.

N. BRIGGS,
COLONEL, I.M.S.,
President, Medical Council,
United Provinces.

R. N. SHUKLA,
Registrar, Medical Council,
United Provinces.

PUNJAB MEDICAL COUNCIL

PROCEEDINGS OF A MEETING OF THE PUNJAB MEDICAL COUNCIL HELD IN THE COMMITTEE ROOM OF THE OFFICE OF THE INSPECTOR-GENERAL OF CIVIL HOSPITALS, PUNJAB, LAHORE, ON SATURDAY, 30TH NOVEMBER, 1946, AT 10 A.M.

BEFORE transacting the business the President on behalf of the Punjab Medical Council extended a welcome to Dr. K. R. Chaudhri a newly elected member to the Punjab Medical Council in place of Khan Bahadur Dr. K. A. Rahman, O.B.E.

The Punjab Medical Council also placed on record their deep appreciation of the services of Khan Bahadur Dr. K. A. Rahman during the long period of 24 years during which he has been a member of the Punjab Medical Council.

1. The proceedings of the last meeting held on the 10th April, 1946, were confirmed.

2. Considered the recommendations of the Executive Committee of the Punjab Medical Council held on the 12th November, 1946 (Appendix).

Resolved (i) that the recommendations of the Executive Committee of the Punjab Medical Council held on the 12th November, 1946, at item nos. 1 and 3 to 16 be approved.

(ii) Item no. 2. Resolved that the name of Dr. Miss Jaywanti C. Gujar, M.D. (Paris) be recommended to Government for registration on the Punjab Medical Register.

(iii) Item no. 17. Resolved that Dr. Shankar Dass Mehra be further advised that the Council views with disfavour any case in which suspicion arises from certificates given without personal examination of the case at the actual time. The Council directed the President to advise Dr. Shankar Dass Mehra that the procedure adopted by him is irregular.

3. Considered the appointment of a member on the Punjab Nurses Registration Council.

Resolved that Dr. Mrs. Shakuntla Prem Chandra, M.B., B.S., be appointed a member of the Punjab Nurses Registration Council. Carried.

4. Considered the audit and inspection note on the accounts of the Punjab Medical Council for the period July 1945 to June 1946.

Resolved (i) that the audit note be recorded and that sanction be accorded to :—

(a) The purchase of a daily *Tribune* for the office of the Punjab Medical Council.

(b) To the advance of a sum of Rs. 250 to Clerk Balwant Singh out of his Provident Fund Accounts.

(c) To the expenditure of Rs. 20 incurred in connection with the fees to members over the sanctioned Budget Estimates.

(d) To the adopting of the scale of stationery sanctioned by the Punjab Government for its employees.

Resolved (ii) that the fee paid to members for attending meetings of the Punjab Medical Council or its Sub-Committees be restored to the previous fee of Rs. 32 from Rs. 20 which reduction was voluntarily offered by the Council in time of financial stress. This should take effect from the meeting held on the 30th November, 1946.

5. Considered the Supplementary Estimates for the year 1946.

Resolved that the Supplementary Estimates for the year 1946 be approved.

6. Considered the Budget Estimates for the year 1947.

Resolved that the Budget Estimates for the year 1947 be approved.

7. Considered Punjab Government letter No. 7727-M-46-29127, dated 11th November, 1946, re. amendment of rule 40(2) of the rules of the Punjab Medical Council.

Resolved that Government be informed that in the opinion of the Council no amendment in rule 46(2) is necessary. The Council will exercise its functions under rule 40(2) of the Act when it so desires—and generally as an august body this power is necessary—but notes that it may in cases where less punishment is necessary act under Section 10(2) of the Act. The Council considers this legal and will invariably specify the Section of the Act or Rule under which such action is taken.

8. Considered letter No. 1-97/46/PH(ii), dated 25th November, 1946, from the Public Health Commissioner with the Government of India, re. a yellow fever inoculation certificate issued by Dr. Kh. Ahmad Sadiq, M.B., B.S.

Resolved that Dr. Kh. Ahmad Sadiq be served with a notice to appear before an extraordinary meeting of the Punjab Medical Council—which will be held for the purpose in the month of January 1947—to show cause why his name be not removed from the Punjab Medical Register.

(ii) Resolved that Lieut.-Colonel C. M. Nicol, D.P.H., I.M.S., Director, Public Health, Punjab, be requested to prepare a detailed note on the yellow fever problem and the technique required for its inoculation which be placed before the meeting called especially to consider the case of Dr. Kh. Ahmad Sadiq. The Council considers that the matter is of such an importance to the province that special steps are necessary to advise the profession in this matter.

9. Considered whether the booklet (*Tuberculosis*) issued by Khan Sahib Dr. Riaz Ali Shah a registered medical practitioner constitutes an advertisement.

Resolved that the explanation of Khan Sahib Dr. Riaz Ali Shah be called for in the matter and he be further asked to state and furnish the advertisements issued for the sale of his book *Tuberculosis* in the various papers and journals and also the comments published in the Press on this publication. This explanation be considered at the meeting to be held in January 1947.

COLONEL, I.M.S.,

President, Punjab Medical Council.

(Sd.) HANS RAJ,

Registrar, Punjab Medical Council.

APPENDIX

PROCEEDINGS OF A MEETING OF THE EXECUTIVE COMMITTEE OF THE PUNJAB MEDICAL COUNCIL HELD IN THE COMMITTEE ROOM OF THE OFFICE OF THE INSPECTOR-GENERAL OF CIVIL HOSPITALS, PUNJAB, LAHORE, ON TUESDAY, 12TH NOVEMBER, 1946, AT 2 P.M.

1. Considered the application of Dr. H. M. Jagan Nath Rao, M.B., B.S. (Mysore University), for registration on the Punjab Medical Register.

Recommended that the name of Dr. H. M. Jagan Nath Rao, M.B., B.S. (Mysore University), be registered on the Punjab Medical Register and the qualification of M.B., B.S. (Mysore University) be brought on the schedule of qualifications registrable on the Punjab Medical Register.

2. Considered the application of Dr. Miss Jaywanti C. Gujar, M.D. (Paris), 1942, for the registration of her name on the Punjab Medical Register.

Recommended that a reference be made to the Bombay Medical Council with regard to their attitude in respect of Indian Nationals holding foreign medical degrees and the reply be placed before the next meeting of the Punjab Medical Council where the case of Dr. Miss Jaywanti be further considered.

3. Considered the application of Dr. Mrs. K. Selzer, M.B. (U. Rome), for registration of her name on the Punjab Medical Register.

Recommended that in view of the fact that she advertised herself in October 1937, her name be not registered on the Punjab Medical Register.

4. Considered the case of Dr. Bakhtawar Singh Jain, L.R.C.P. & S., who was registered provisionally on the Punjab Medical Register.

Recommended that a reference be made to the authorities of the Royal College of Physicians and Surgeons, enquiring as to whether Dr. Jain still continues to hold their qualifications in view of the fact that his name has been removed from the British Medical Register and his case be reconsidered when the reply is to hand.

5. Considered letter dated the 5th June, 1946, from the Superintendent of Post Offices, Ambala, re. a medical certificate issued by Dr. Sumer Chand Gupta and the explanation of Dr. Gupta thereon.

Recommended that no action is called for against Dr. Sumer Chand Gupta.

6. Considered the representation of Dr. Faqir Chand for the restoration of his name to the Punjab Medical Register.

Recommended that the name of Dr. Faqir Chand be restored on the Punjab Medical Register and that the State Medical Faculty be approached to amend their rules so that it may not be obligatory on the Faculty to declare the diploma of a person whose name has been removed from the Punjab Medical Register void.

7. Considered letter dated 6th May, 1946, from the New India Literature Co., Lahore, re. publication of career sketches of the registered medical practitioners.

Recommended that the publication of facts about the career of a registered medical practitioner is permissible but the statement should not savour of an advertisement, as does the instance on which the Council have been asked to deliberate.

8. Considered the explanation of Dr. Kishan Chand of Sialkot City re. association of his name with 'Dr. Kishan Chand & Co., Ltd. Chemists'.

Recommended that Dr. Kishan Chand be asked to take steps to disassociate his name with the firm.

9. Considered letter no. 13864, dated 11th December, 1946, from the Civil Surgeon, Amritsar, re. a certificate issued by Dr. Gopal Singh Sekhon, L.S.M.F.

Recommended that no action is called for against Dr. Gopal Singh Sekhon.

10. Considered letter no. 7704, dated 24th September, 1946, from the Civil Surgeon, Amritsar, re. a medical certificate issued by Dr. Sant Dass, M.B., B.S.

11. Considered letter, dated 27th August, 1946, from Dr. Harish Chander, re. a printed postcard circulated by Dr. Kirpa Ram Sud, M.B., B.S., and the explanation of Dr. Kirpa Ram Sud thereon.

Recommended that Dr. Kirpa Ram Sud, M.B., B.S., be served with a notice to appear before the Punjab Medical Council and show cause why his name be not removed from the Punjab Medical Register.

12. Considered the explanation of Dr. Shiv Lal Bhatia, L.S.M.F., re. an Urdu poster circulated about his eye clinic.

Recommended that Dr. Shiv Lal Bhatia be advised in his own interest to take steps to see that his name is not advertised directly or indirectly.

13. Considered the question of the removal of the name of Dr. Harnam Singh who has been convicted by a Court of Law under the Defence of India Rules for granting untrue medical certificates.

Recommended that the name of Dr. Harnam Singh be removed from the Punjab Medical Register and that the President be authorized to restore his name on application.

14. Considered the question of the removal of the name of Dr. Narsingh Dass Gulatia, L.S.M.F., from the Punjab Medical Register in view of the fact that

he has been convicted under the Dangerous Drugs Act.

Recommended that the name of Dr. Narsingh Dass Gulatia be not removed from the Punjab Medical Register.

15. Considered endorsement no. 9090-C.II., dated 9th September, 1946, from the I. G. G. H. Punjab, re. Captain Gajinder Singh who has been declared insane.

Recommended that the Punjab Government be requested to make suitable provision in the Punjab Medical Registration Act amendments to which have already been suggested by the Council to authorize the Punjab Medical Council to remove the name of an insane registered medical practitioner from the Punjab Medical Register.

16. The Executive Committee agreed to raising the price of Annual Medical List for the year, 1946, from Rs. 5 to Rs. 8 in view of the high cost of printing.

17. Considered the explanation of Dr. Shankar Dass Mehra, re. a medical certificate issued by him.

Recommended that no action is called for against Dr. Shankar Dass Mehra.

Registrar, Punjab Medical Council.

WOMEN DOCTORS' TRIUMPH

SUCCESS OF WOMEN'S HOSPITALS IN AUSTRALIA

By SUSAN BARRIE

Canberra, Australia

THE Rachel Forster Hospital for Women and Children, Sydney's newest and most modern hospital, is staffed and conducted by women for the benefit of women. It was founded by a woman, and women have the last word in its administration.

To-day, it is one of the outstanding organizations of Australia's largest city, but it rose from a humble beginning. Its history is also a history of women's fight for recognition in the medical profession.

Directly after the first world war, it was difficult and often impossible for a woman doctor to obtain a hospital appointment in Australia, and opportunities for specialization were few and far between. There was in fact a very strong prejudice against women in the medical profession. But Dr. Lucy Gullett and Dr. Harriet Biffin were not deterred. They were two resolute and independent women, and they went to work to establish a hospital which would serve a twofold purpose; it would provide treatment for necessitous women, and it would at the same time form a centre for work among women doctors and a training school for women specialists in every field.

They began in 1922, with Rs. 10,708 subscribed by sympathizers, and started a 'new hospital for women and children' in a small dilapidated house in Surrey Hills, a densely populated suburb of Sydney.

In the words of Lucy Gullett, the hospital was 'a tiny place, and we could only treat out-patients, but it was the beginning of the fulfilment of a dream'. On the first day it was opened, one solitary patient attended, and the two women felt that her courage almost merited a decoration. But during the ensuing year they treated more than 6,000 women.

From that time onward, the hospital made rapid and continuous progress. The original conception of a women's hospital grew out of all recognition, until the two founders were amazed by the result of their effort.

In 1924, so great was their progress, that they were compelled to buy a larger building to house their growing organization. This time it was in Redfern, a

nearby suburb. It was here that the new hospital was opened in the following year, and named the Rachel Forster Hospital for Women and Children, in honour of Lady Forster, wife of the then Governor-General of Australia, who had been interested in the work since it began.

Year by year new departments were added to the hospital; departments for venereal diseases, dentistry, physiotherapy, ear, nose and throat work, psychiatry, child guidance and rheumatism treatment. In 1932, a new wing was built to cater for the rapidly increasing number of out-patients and to establish a pathology department.

By 1937, the efforts of the women doctors were rewarded by Government recognition of the Rachel Forster as a public hospital. Up to that time the hospital had provided all its own funds, but had never been in debt. In that year, when annual attendances of out-patients numbered 60,000, it became clear that expansion was necessary, and the Minister for Health supported the proposal to build a new hospital that would provide accommodation for 124 in-patients. Land was bought in Redfern, near the old site, and a new hospital was built in 1941 at a cost of Rs. 14,99,170.

To-day the Rachel Forster Hospital is housed in an ultra-modern, stream-lined building which reflects the feminine touch in its pastel colour-scheme and clever combination of the utilitarian with the decorative. The hospital has been planned to give the maximum of light, and glass is used to good effect in all sections of the building. On the north-eastern side of the five-story block, where the sun streams into the wards across spacious verandahs, the walls and ceilings are washed in cool, pale shades of green and blue. On the shady side of the building, rooms are decorated in warmer shades of soft pink and yellow. There is a specially designed children's ward, equipped with a solarium, and the nurses' quarters are especially attractive with comfortable gaily furnished sitting-rooms and a pleasant bedroom for each girl. Bathrooms, washing, drying and ironing rooms are equally modern and convenient.

Dr. Mary Puckey, a graduate of the Sydney University, administers the hospital, and combines the jobs of Chief Executive Officer and Medical Superintendent. She is assisted by four resident women doctors and a visiting staff by forty-five doctors, of whom nine are men. The board of directors is composed entirely of women, under the leadership of a woman president. The office staff is composed of women, and a city office run by women, deals with publicity and collection of funds.

The x-ray and pathology departments and the dispensary are also staffed by women, and an extensive social services department is in charge of women almoners.

The Rachel Forster Hospital has now one of the largest out-patient departments in Sydney, last year it cared for 50,000 patients, and the in-patients numbered 1,600. The venereal diseases clinic for women is the largest in New South Wales.

The new hospital, completed just before the war, was planned to allow for growth and expansion. The present main block will take a complement of 124 in-patients, but plans for development include additional nurses' quarters, an up-to-date maternity block, and a new convalescent home, to be called the Lucy Gullett Convalescent Home, in recognition of the pioneering work done by the founder, Dr. Gullett.

The Rachel Forster Hospital has an excellent system of finance. Besides periodic special drives for funds, there are two continuous sources of revenue, the Rachel Forster Hospital 'Centres' (groups of voluntary helpers who organize fêtes, dances, card parties, egg days, and collect during drives for funds), and an outdoor collection scheme.

Outdoor collections are conducted by a team of women who work on a roster system with collection boxes, or make regular 'house-to-house' visits in

allotted districts. There are 25 to 30 of these workers, under the direction of a special supervisor. They join the hospital staff on a fixed salary, receive no commission, but are all enthusiastic about bringing in good donations for the hospital.

Recently a new source of revenue was devised through establishment of the Rona Convalescent Home, where women and children can recover from their illnesses in healthy, congenial surroundings. Profits from fees paid by these patients goes to general hospital funds.

The hospital is subsidized by the Australian Government at the rate of Rs. 3-3 a day for each occupied bed.

Patients admitted to the hospital can choose to occupy 'public' or 'intermediate' wards, or private rooms. If they enter a public ward, they pay nothing, neither hospital nor medical fees. Intermediate ward patients pay Rs. 45 a week in a four-bed ward, or Rs. 56-10 a week in three-bed wards, less the Rs. 3-3 a day (Rs. 22-5 a week) allowed to the hospital under the Commonwealth Government Benefit Scheme. Patients who occupy private rooms pay Rs. 67-8 a week, again less Rs. 3-3 a day subsidy. Both private and intermediate patients pay their own doctors' fees, and for special treatment.

There is no means test—patients may be 'public' or 'private' by their own choice.

There is no charge for medical attention to out-patients, but those who can afford it, pay cost price for their medicines. The highest price ever paid by one patient is approximately Re. 0-9-3 but many pay nothing.

The hospital is not unique in Australia, for it was built on the pattern of the Queen Victoria Hospital, in Melbourne, Victoria. The Melbourne Hospital, too, was founded for women by women, to be run by women. The history of these two great institutions has shown that in Australia, at any rate, women in the medical profession have met men on their own ground, and proved their equality.

HUNDRED YEARS OF HEALTH SERVICES

MANY public authorities in Britain will this year hold health exhibitions to celebrate the centenary of the first medical officer of health appointed in Liverpool in January 1846.

Liverpool's lead was followed quickly by the City of London, which appointed the famous surgeon, Sir John Simon, then only 30 years old.

In 1846, the expectation of life was 20 years; to-day, it is well over 50. The mortality rate of babies in large towns was 150 per 1,000 births; to-day, it is less than 50 for the whole of Britain. In 1847, 23 people out of every 5,000 living in London died from tuberculosis; to-day, the death rate is 4 per 5,000.

Scarlet fever, whooping cough and measles killed 21 out of every 10,000 Londoners; in 1945, deaths were 1 in 10,000. A century ago, deaths from smallpox in London were 22 per 50,000 of the population; in 1889, there was only one, and in 1945 none.

Eight out of 10 babies who were doomed to die in 1847 now live on.

United Kingdom Publicity Services.

LONDON,
16th January, 1947.

L.T.M. COURSE 1947 AT THE CALCUTTA SCHOOL OF TROPICAL MEDICINE

THE three months' course of instruction for the Licentiate in Tropical Medicine will begin from the 15th July, 1947. Applications for admission should be submitted as early as possible to the Director, School of Tropical Medicine, Calcutta.

Public Health Section

SICKNESS ABSENTEEISM AND RECORDING IN INDIAN INDUSTRIAL ESTABLISHMENTS

By E. LLOYD JONES, M.D. (Vict.)
MAJOR, I.M.S. (F.C.)

WITH increasing industrialization in India the problems of absenteeism of all kinds are bound to become more and more marked. There is no need to elaborate the ill effects of absenteeism upon production, but that they can be most serious is universally accepted. When workers are absent, often without warning, valuable machinery is allowed to stand idle, or is not used to its full productive capacity, which results not only in loss to the employing firm, but eventually to the workers and the community as well.

Absenteeism due to other causes than sickness comes within the province of the works personnel department, or the psychologist working in the personnel department rather than that of the works doctor, or the general practitioner working in an industrial area. This type of absenteeism will therefore not be discussed further.

Absenteeism which is due to sickness can be divided into two main classes, that which in the present stage of development of medical knowledge may be regarded as inevitable, and that which can certainly be prevented. The main interest of the works doctor, or the general practitioner working in an industrial area is in that class of sickness absenteeism which can be prevented, either by preventive health measures, or by early and efficient treatment of the diseases which cause it. From the restricted point of view of pure absenteeism, it does not matter very much whether the sickness is directly connected with the nature of employment, such as for example lead poisoning among pottery workers, or whether it has no apparent connection with the nature of employment, such as for example venereal disease or typhoid fever. Both types of sickness cause absence from work, and are therefore the close concern of the works doctor.

The problem of reducing sickness absenteeism can only be tackled adequately if there is accurate information as to its total amount, for comparison with similar figures in other countries, and also for purposes of comparison between sickness rates in different industries in India, or between different factories or groups of factories, or even between different departments of one factory. Data of this nature is readily available in other countries where there is a large industrial population. For example in the United Kingdom the total number of days lost annually through sickness by workers insured

under the National Health Insurance Act before the war was about 15. In America the figure was rather lower. In Germany from 1922 to 1931 the figure was about 12 days per worker per year. Information on total sickness absence from all causes in Indian industrial establishments, however, is at present very sketchy, since very few such establishments keep accurate records of sickness absence, and many firms maintain no records at all.

Furthermore, it is quite clear that if any real progress is to be made towards combating sickness absenteeism, not only is it necessary to know how much total sickness there is, but also to ascertain in the first instance on broad and general lines what is the nature of that sickness, how much of it is due to the immediate conditions of employment, how much can be regarded as inevitable, and how much is definitely preventable. To do this necessitates some form of sickness recording.

The possible methods of sickness recording may be divided into two main categories, that based on the works timekeeper, and that based on the works medical officer. Both methods are in common use in other countries, and each has its advantages, a combination of both, of course, being best of all.

Sickness recording by the works timekeeper

Sickness recording based on the works timekeeper will be dealt with first. In this method the works timekeeper makes an appropriate entry on the workman's daily time sheet showing that he is absent, and various symbols or signs may be adopted to reveal the alleged cause of the worker's absence. The information derived in this way is very useful. For example it gives information about genuine reasons for absence from work apart from sickness. But from the industrial health point of view its value is rather limited. If an accurate estimate is to be made of sickness as a factor in absenteeism it is important to be as certain as possible that any sickness recorded shall be genuine. It is not to be accepted that every time a man asks for time off work on account of sickness that man is necessarily ill and unfit for work. A man wants a day or half a day off to see a hockey match or for some other purely personal reason. The easiest way is to send a note to his employer to say that he has fever, or diarrhoea. In this way he does not get blamed for his absence, which he probably would do if he merely said that he wanted to go to the hockey match. This situation is of course not peculiar to India by any means. It is very difficult to check up on this type of absence of short duration. It may be perfectly genuine, but much more often it is false. One way to reduce it is to insist that not even one day's absence from work will be

permitted without a medical certificate. In most works this would be impracticable.

Even if the certificate of an outside medical practitioner is accepted as evidence of incapability for work there are many sources of possible error. Medical practitioners all over the world have a pronounced objection to any form of clerical work and certificates are often issued with little regard to strict accuracy of diagnosis. The doctor is not always to be blamed for this. It is often very difficult to give a firm opinion as to whether a man is fit for this work or not in the absence of definite physical signs. All practising doctors must be familiar with the man who comes and says he has severe neuralgia, or feels sick or dizzy, or that he had a high temperature earlier in the day. It would need a magician to say in all cases whether that man is genuine or not and few doctors would willingly refuse him a certificate, in case there happened to be something seriously wrong with him which was not apparent at the time of examination. In this way a man may obtain a sickness certificate, and be shown as sick, when in point of fact he may have been perfectly well, and merely wanted to go to see the hockey match. The certificates will ultimately be collected in the office of the works timekeeper, but they will be of limited value for statistical purposes, as their degree of detail and accuracy will be insufficient to draw very much in the way of useful conclusions from them. Information as to sickness absenteeism gathered in this way must therefore be regarded with a very cautious eye. At the same time this form of sickness recording is the only one possible when there is no comprehensive system of health care for workers, or in the absence of a medical scheme in connection with the works itself and although it is limited in value, it is very much preferable to nothing at all.

Sickness recording by the works medical officer

Where there is a system of medical attendance in connection with a factory or a group of factories, much better methods of sickness recording are possible, provided there is a reasonable degree of continuity of employment, and the medical facilities are such that the works doctor has sufficient time at his disposal to examine and treat his patients properly, and to keep brief clinical records of those patients he treats. Experience shows that in ordinary conditions a doctor can be responsible for about 2,000 workers, provided he is employed full time, and is not allowed to divide his attention between his works duties and private practice. A total 'list' of 2,000 workers gives an average daily attendance at the dispensary of about 60 patients, which, if the doctor spends five hours daily seeing patients in the dispensary, allows of an average of five minutes with each patient.

The basis of the system of sickness recording based on the works doctor is in the individual medical record envelope, and medical record

eards for each worker. It is of course essential that a worker should be assigned to one specific dispensary and preferably to one individual doctor. Each worker on joining the factory is given a serial number and a personal medical card, which is his evidence of his entitlement to medical treatment. If there are several dispensaries or doctors attached to a large works, he should be allowed to choose the one he would like to attend, provided there are vacancies. Having once been assigned to a dispensary or a doctor for treatment he should not be allowed to change except at certain fixed periods of the year, such as for example the end of the year, or the half year. Emergency treatment may of course be obtained at any dispensary. The assignment of a worker to one dispensary is necessary in order to obtain some degree of continuity of treatment and recording. A medical record envelope (see figure 1) is then

<u>WORKS MEDICAL SCHEME</u>

sent to the dispensary to which the worker has been assigned, where it will be filed alphabetically until such time the worker requires treatment.

When the worker requires treatment and attends the dispensary he first of all collects his medical record envelope from the clerk, who

inserts in it a medical record card (see figure 2). The worker hands this to the doctor. Having examined the patient the doctor makes entries in the appropriate columns on the card showing the date of attendance, whether a certificate of incapacity was issued, short clinical notes, and a diagnosis. He also enters in the appropriate column the disease group into which the diagnosis falls. This requires further explanation.

Medical Record Card [1/2 size]

Fig. 2.

In order to obtain information as to the different types of sickness which are causing absenteeism, it is necessary to classify sickness and accidents into groups, which can be recorded on the medical record cards. The type of medical record card used will vary according to the needs of a particular factory or group of factories, and according to the degree of detail into which it is proposed to enter. Probably the best is the punched card of the 'Findex' type as illustrated in figure 2 which permits of easy sorting by hand without the use of expensive and complicated machinery. The card is ready punched with holes along each side. Each hole may be accorded any significance according to the needs of any particular factory, but the first 20 holes or so should be retained for group classification of diseases and

numbered 1 to 20 accordingly. The remaining holes may be used for sorting workers from different sections of a factory, or from different factories from among a group of factories.

There is no special standard for the classification of sickness and accidents into groups, except that the number of groups should not be too large, otherwise the whole procedure becomes unwieldy. Each group should, however, be assigned a number, and it is this number which the doctor enters on the medical card of each worker attending for treatment. The following is a fairly simple classification of diseases into groups, which it is considered should generally be suitable for conditions in Indian industrial establishments. It will be observed that it provides not only for classification of diseases, but also for accidents occurring in the course of employment, and for industrial diseases.

Group 1. General infections, but excluding malaria, syphilis, and tuberculosis.

Group 2. New growths, both simple and malignant. All sites.

Group 3. Diseases of nutrition and metabolism, and of the endocrine glands.

Group 4. Malaria.

Group 5. Other undiagnosed fevers.

Group 6. Dysentery, amœbic, bacillary, and diarrhœa.

Group 7. Diseases of the blood and circulatory system.

Group 8. Diseases of the respiratory system, but excluding tuberculosis and new growths.

Group 9. Diseases of the digestive system, but excluding tuberculosis, new growths, dysentery, typhoid fevers and diarrhœa.

Group 10. Diseases of the genito-urinary system, but excluding syphilis, gonorrhœa, tuberculosis and new growths.

Group 11. Pregnancy and the puerperium, and the diseases thereof.

Group 12. Diseases of the skin and cellular tissues, but excluding occupational dermatitis.

Group 13. Diseases of the nervous system and sense organs, and mental diseases, but excluding syphilis, tuberculosis and new growths.

Group 14. Rheumatic diseases.

Group 15. Venereal diseases, including syphilis and gonorrhœa, all sites and stages.

Group 16. Tuberculosis, all sites and stages.

Group 17. Accidents arising in the course of, and as a result of employment.

Group 18. Scheduled industrial diseases, and other diseases arising in the course of, and as a result of employment.

Group 19. Unclassified conditions.

To return to our patient. The doctor has entered in the appropriate column the number of the disease group into which the diagnosis falls. The medical record card is then returned to the clerk, who cuts out the edge of the correct punched hole on the card, converting the hole into a slot. The card is then replaced in

its envelope, and returned to its proper position in the filing box.

It will be a simple matter to extract the cards of all the workers who have received treatment during the quarter, and to find out how many working days have been lost by all the workers in each particular disease group. This is done by inserting a long needle through the holes of each disease group in turn in the bundle of cards, and shaking the bundle, when all the cards in the group concerned will fall out, since the original holes have been converted into slots.

In practice it will be found convenient to keep one side of a medical record card for one year, and the reverse for the following year irrespective of whether the space on the card has been completely filled or not. At the end of each quarter the card should be ruled right across with red ink. All this sounds complicated on paper but in practice it is very easy.

What is the nature of the information which it is possible to obtain in this way? Suppose we assume a factory or group of factories employing 4,000 workers. This would necessitate the employment of two doctors. By the method already described it would be an easy matter at the end of each quarter to ascertain how many working days have been lost during the quarter in each of the disease group. For example you may find that in one particular quarter 8,000 working days lost, 1,000 have been lost owing to diseases of the respiratory system. If the factory is one where there is a lot of dust you would then naturally try to find out whether there was any connection between the dust and the chest troubles, and if there were, it would certainly be well worth while from everyone's point of view to take some trouble to deal with the free dust in the atmosphere by means of some mechanical method of dust extraction.

This system of recording then would give you a detailed picture of the health state of the workers in any factory or industry. In addition to that it would also ensure that for every worker there was a written and permanent record of his state of health. There is no need to stress the immense value of such a record from the point of view of individual treatment. There is no danger of the man's doctor forgetting his patient's previous conditions; his weight and other valuable data will be periodically recorded; if he changes to a fresh doctor there will always be his previous medical history available for ready reference.

The system as a whole has other decided advantages. Since the doctor will have a fairly stabilized clientele from among the workers he will gradually get to know his patients as individuals, get to know their family circumstances, their difficulties, their weak points from the health aspects. He will thus be able to advise them with regard to their health instead of merely advising them about their diseases, that is adopt a positive attitude towards the

health of the individual and the community. Provided a doctor is not overloaded with patients there is no reason why periodical examinations of the patients in his list should not be made quite apart from any question of illness. The findings at such examinations could be recorded on a separate health card which could be inserted into the medical record envelope. In this way a constant check would be kept on the health state of each individual worker, and diseases often detected in the earliest stages when they are most amenable to treatment.

This is not a plea for recording for the sake of recording. The advantages of proper record of sickness are beyond all possible doubt. Nor are those advantages confined to one particular class. The worker benefits, and experience in other countries, notably the United States of America, has shown clearly that the institution of a proper system of medical recording, such as has been described, results in the long run in actual monetary advantage to employers, and to industry and the community as a whole. If India is to establish her rightful place in the industry and commerce of the world, she must be prepared to adopt modern scientific methods, not only in the actual machinery of production, but also with regard to the health and well-being of the workers engaged in that production. For this a proper system of recording of sickness occurring in industry is an essential prerequisite.

THE RÔLE OF THE WORKS DOCTOR, OR GENERAL PRACTITIONER, IN INDUSTRIAL MEDICINE

By E. LLOYD JONES, M.D. (Vict.)
MAJOR, I.M.S. (E.C.)

WITH increasing industrialization in India, more attention is being paid to the Indian industrial worker and his health and well-being.

It is a common fallacy that to obtain satisfactory results in industrial medicine highly-trained specialists and technicians are essential in the first instance. This is reflected in a tendency to send doctors overseas for prolonged training in industrial medicine. That a large number of such specialists will ultimately be required is undoubted, but the fact remains that the corner-stone in any comprehensive scheme to improve the health of the industrial worker is the ordinary works doctor, or failing him the general practitioner working in an industrial area.

Unfortunately in India at the present day, the works medical officer and the general practitioner are largely wasted so far as industrial health is concerned, since very little is done in the way of recording the sickness and accidents they treat, or making any attempt to correlate the work of the various doctors concerned. In certain Indian industrial establishments there may be

one or more medical officers attached to a factory or a group of factories. In the majority of factories, however, there is not even this, and the workers are left to the mercies of whatever medical facilities are available in the town in which the factory is situated, which are often very meagre. Even where there is a factory medical service in existence the function of the medical officer is only too often merely to treat sick workers when they apply for treatment, either for sickness or for the results of accidents within the factory. Often the number of workers for whose treatment the doctor is responsible is very large, so that even the treatment provided is perforce given in a hurried and perfunctory fashion. In very few factories is there even the simplest method of sickness recording. The result is that what medical work there is in connection with works medical schemes is carried on in a haphazard fashion, and although individual medical officers may have their own ideas as to the various types of sickness which cause absenteeism in the industry concerned, they have no means of correlating the material they gather, or of comparing notes with medical officers of other and similar establishments.

If India is to attain her rightful place in world industry and commerce, Indian industrialists must realize that the health of the worker is one of their most valuable assets, and must foster any attempt to improve it by taking a live interest in the health and welfare of their employees. The institution of a system of sickness recording is one of the first steps which should be taken to attain this objective.

The progress of industrial medicine in other countries where there is a high degree of industrialization indicates the path to be followed, and statistics show quite clearly that the higher the development of the works medical services in any country, the better is the health of the worker, and the less is sickness absenteeism. In fact figures of sickness absenteeism bear a very close relationship to the degree of development of factory medical services. In the United States of America, where factory medical services are the rule rather than the exception, the sickness absenteeism rate is about 9 days per worker per year, whereas in England, where factory medical services, although increasing, are still relatively undeveloped, the sickness absenteeism rate is probably half as much again as this.

The way to reduction of sickness absenteeism lies through the works medical officer, but it is a prerequisite that there should be a proper system of sickness recording, so that the results of his work shall be available for statistical investigation, and preventive measures instituted in order to take fullest advantage of the information obtained.

There could be no better illustration of the possibilities of the ordinary general practitioner in connection with industrial diseases than that

afforded by a condition well known in the cotton industry in Great Britain, namely, mule spinner's cancer of the scrotum. Clinically this is an epithelioma starting in the skin of the scrotum. In the early stages its progress is slow, but it fairly quickly gives rise to secondary growths, and when it does so is fatal. No claims under the Workmen's Compensation Act in respect of mule spinner's cancer were made until about 1923, but there is no doubt that cases were fairly common in Lancashire certainly before 1900, and that the condition was well recognized by general practitioners practising among cotton operatives. When the present writer was assistant to the late Dr. Sidley of Eccles in 1922, he was shown a series of private case histories which proved that Dr. Sidley had been quite familiar with condition as far back as 1906, and had a very good idea of its cause. There can be little doubt that other practitioners in the area also recognized the condition. But since there was no organized system of sickness recording in general use in England in those days, and as general practitioners are as a rule very shy of writing to the medical press, each man kept his knowledge to himself, and the disease was never described in any of the medical or surgical papers, or in any textbook.

About 1912, a medical student at the Manchester Royal Infirmary, the late S. R. Wilson, was shown by his teachers several cases of cancer of the scrotum which were described as chimney sweep's cancer. Being an alert individual, Wilson noticed that the patients suffering from chimney sweep's cancer did not seem to be chimney sweep's at all, but were almost invariably cotton spinners. He was so impressed by this that he concluded that there must be some connection between cancer of the scrotum and being a cotton spinner. No special notice was taken by the profession at the time, but a few years later, Wilson, together with Mr. A. H. Southam, made much more complete investigations into the condition, concluded that it was caused by the mineral oil used in lubrication of the machinery, and published his findings in the *British Medical Journal*. Since then there has been a great deal of work done in the subject, and it is now proved that Wilson's ideas were correct, and that the cause of mule spinner's cancer is certain carcinogenic substances present in the mineral oil used in the lubrication of spinning mules. Work is still proceeding in order to ascertain the best method of eliminating these substances from the oil used, with very considerable success. That is, of course, where the expert, or rather the team of experts, comes in, but the fact remains that the original discovery of the connection between cotton spinning and cancer of the scrotum was made by general practitioners and a medical student, and would have been described in the literature perhaps twenty years earlier than it was had there been some method of recording and classifying sickness in general use in England at the time.

Mule spinner's cancer also provides very strong support for regular systematic examination of workmen apart from actual sickness. Clinically, it is practically never seen in men who have been engaged in the industry for less than twenty years. Moreover, it is very amenable to treatment in the earliest stages, one application of radium often resulting in complete cure. It is, therefore, apparent that if examination of cotton spinners who had been engaged in spinning for over twenty years were carried out at regular intervals, say every six months, the disability and mortality from the disease could be reduced to negligible proportions. Mule spinner's cancer has already cost the cotton industry in Great Britain over 20 lakhs of rupees in compensation for deaths alone, in addition to a large sum in compensation for disability arising from the disease. Quite apart from the tragic loss of life, most of this money could have been saved by regular examination of operatives, which would not have required the services of specialists, but could quite easily have been carried out by ordinary medical practitioners, provided proper records of their examinations were maintained. The moral for Indian industrialists is clear.

India is at the commencement of her industrial and economic development, and is in the fortunate position of being able to profit from the mistakes of other countries where development has taken place earlier. Among the most costly of errors committed in Europe has been neglect of provision of medical services in direct connection with industrial establishments, and of statistical recording and analysis of the work of medical services where they have been established. These errors are easily avoidable. No elaborate administrative machinery is required. The principles are easy to follow and to adopt.

A large number of doctors released from army service who have been accustomed to a high level of professional treatment, and to the keeping of systematic records of various kinds, are now in search of peace-time employment. No more profitable way of utilizing the services of some of these men could be found than by absorbing them in medical schemes in connection with Indian industry.

USE OF CRUDE OIL AND BLEACHING POWDER IN CONTROLLING FLY BREEDING IN COMPOST TRENCHES

By K. G. JOSHI, M.Sc. (Agr.), Ph.D.
Biochemist to C. P. Government

and

-V.-R. DNYANSAGAR, M.Sc.
Assistant Biochemist, Department of Agriculture, C. P.
and Berar

In a large number of municipal towns in India, the methods of disposal of town wastes

like night soil and *katchra* are highly insanitary and wasteful. The *katchra* dumping grounds and the night soil trenching grounds have often proved to be dangerous sources of fly breeding. For some years now, the compost method has been recommended as a satisfactory system of disposal of town refuse. It has proved to be of higher sanitary standard and has been responsible for better utilization of the wastes as manure.

Since the inception of the Compost Scheme (August 1943) as an activity of the Food Production Drive in this country, the insanitary old methods of disposal have been replaced by the Bangalore Method of Composting Refuse in more than 300 municipal centres. The public health authorities of most of these centres have now been convinced of its sanitary superiority over the old methods. In view of certain criticism, however, in regard to the efficacy of the method in mitigating fly nuisance, a critical investigation on this aspect was undertaken and an account of some observations (Joshi and Dnyansagar, 1945) has been already published in this journal.

It was observed that the number of fly maggots and pupæ in compost trenches is very low during winter and summer months and that the maximum temperature developed in the compost mass within first week after processing was more than 65°C. which was considered lethal for fly eggs, maggots and pupæ. Ordinarily hence compost method of disposal of refuse can be considered effective enough in controlling fly breeding during winter and summer months; during the rainy season, however, considerable variation in the temperatures occurred and the maximum temperature usually did not exceed 45°C. The low temperatures of compost mass and the humid atmospheric conditions do not check fly breeding effectively. Our observations, however, showed that only 10 to 20 per cent of the pupæ in the compost trenches could reach the fly stage, showing thereby that composting could minimize fly breeding to that extent.

The necessity of employing some specific measure to control the small amount of fly breeding that occurred in rainy season was thus seen. Such a measure should be workable under conditions existing in the rainy season. Another important consideration is the cost. The compost manure is generally sold at a cheap rate of 8 to 12 annas per cart load. Since the municipal committees expect the compost depots to be at least financially self-supporting, there is very little margin for adopting any costly method of controlling fly breeding.

Various methods for fly control are known, e.g. employing fly papers, fly traps, chemical sprays, thermal methods such as Fay's (1936), electric screens, earth plasters as suggested by Issac (1944), etc. Acharya and Rao (1945) have recently suggested the tarred hessian cloth method which is a modification of Issac's plaster

method. In actual working, however, considerable difficulties have been experienced for its successful practical application. The tarring of cloth, covering the trench up to a particular period, etc., require much close supervision which is generally lacking in the municipal centres. The method is unwieldy. The need of developing some other simple practicable method for control of fly breeding in compost trenches which could be smoothly operated in various municipal centres was hence felt.

Experimental

Two common insecticides, viz, crude oil and bleaching powder, which are generally stocked by the municipal committees, were employed for the purpose of destroying fly eggs, maggots and pupæ.

In the first place effect of these insecticides was studied on maggots and pupæ in petri dishes. It was observed that almost instantaneous death resulted.

Large-scale trials on compost trenches were conducted thereafter in trenches $5 \times 4 \times 2$ feet which were filled in with 850 pounds of *katchra* and 60 gallons of night soil as per compost technique. Mosquito nets raised properly over the trenches were used as fly traps. Fly counts were taken every day till there was no further emergence of flies.

The average temperature of the compost mass and the count of adult flies that emerged from day to day (an average of four replications) are given in table I. No treatment was given, this

TABLE I

Showing average temperature of compost mass and count of fly emergence in compost trench of $5 \times 5 \times 2$ feet

Day after filling of trench with refuse by compost technique	Average temperature, °C.	Flies emerged
2	40	Nil
3	40	Nil

Total emergence ..		1,434
Emergence per sq. ft. ..		71.7 or 72

being the control trench. Average temperature was taken by introducing a thermometer in the compost mass to a depth of 9 inches and recording temperature at two spots and striking an average of 8 such observations (in four trenches under each treatment).

The above results indicate that a temperature of 45°C. is not effective in killing all the maggots and eggs. Considering that *katchra* and night soil during the rainy season are very highly infested with fly maggots, an emergence of 72 flies per square foot is not very high. The processing of refuse by the compost technique is responsible for checking fly breeding to some extent. The highest fly emergence has occurred from 10th to 14th days.

Along with the above trial using the same refuse in the same quantity, treatment with crude oil and bleaching powder was tried. The rate of application of crude oil was at the rate of 1 gallon per 100 square foot area. It was emulsified in three times the quantity of water and sprinkled on the first day over the surface *katchra* of the compost trench. The rate of application of bleaching powder was 10 lb. dissolved in 5 gallons of water per 100 square foot area. It was also sprinkled on the first day of filling refuse in trenches on the top *katchra* layer. The average temperature and emergence of flies in these treatments are given in tables II and III

TABLE II

Showing average temperature and fly emergence after crude oil treatment of compost trench of $5 \times 5 \times 2$ feet

respectively for crude oil and bleaching powder treatments.

TABLE III

Showing average temperature and fly emergence after bleaching powder treatment of compost trench of $5 \times 5 \times 2$ feet

Day after filling of trench with refuse	Temperature, °C.	Number of flies emerged
2	36	Nil
3	40	1
4	43	Nil
5	45	3
6	43	2
7	41	5
8	39	16
9	39	21
10	40	18
11	40	108
12	40	112
13	37	60
14	37	50
15	37	23
16	36	21
17	37	20
18	37	16
19	30	5
20	35	3
21	35	Nil
Total emergence ..		484
Emergence per sq. ft. ..		24.2 or 24

It is thus seen that as against a fly emergence of 72 per square foot in the compost trenches not receiving any special treatment, the emergence in trenches treated with crude oil at the rate of 1 gallon per 100 square foot and bleaching powder at the rate of 10 lb. per square foot has been lowered to 26 and 24 per square foot respectively. Thus by this simple measure the fly breeding in compost trenches in the rainy season has been reduced by about 65 per cent. It is observed that the temperature of compost mass is not much affected by these treatments and the highest emergence of flies as in the untreated trenches was from the 10th to 14th day.

Double application of insecticides.—The high fly emergence begins on the 10th day after processing of refuse in the trenches. It was, therefore, thought that an additional application of crude oil and bleaching powder on the 8th day would be more effective in controlling fly breeding.

The application of the insecticides was hence done as follows :—

(i) *Crude oil.*— $\frac{3}{4}$ gallon per 100 square foot each time on the 1st and the 8th day after processing of refuse.

(ii) *Bleaching powder.*—6 lb. per 100 square foot each time on the 1st and the 8th day.

The temperature and fly emergence were recorded. The temperatures did not vary much from what was noted in the previous case. The number of flies emerged is given in table IV.

TABLE IV

Showing number of flies emerged in compost trench of $5 \times 5 \times 2$ feet after double treatment with crude oil and bleaching powder on the 1st and 8th day

Total emergence		170
Emergence per sq. ft.		8.5 or 9
		8.0

The double application of both crude oil and bleaching powder on the 1st and the 8th day is very effective in checking fly breeding and lowers it to about 11 per cent as compared to untreated control compost trenches. Our observations published in a previous article in this journal (Joshi and Dnyansagar, 1945) show that the count of maggots and pupæ per square foot in compost trenches in summer months is of the order of 140 out of which emergence of flies might be less than 5 per cent. It could hence be concluded that by double application of either crude oil or bleaching powder the fly breeding in compost trenches in the rainy season can be reduced to the summer level. And the performance of these insecticides can be considered very efficacious.

It was further observed that the application of these insecticides did not interfere in the biochemical decomposition of the manure which ripened in the usual period of 4 to 6 months.

Instructions in regard to use of the chemicals on routine basis.—The following routine method for controlling fly breeding in compost trenches for the rainy season is suggested.

When a trench is completely filled with refuse as specified in the Bangalore method, half to three-fourth gallon of crude oil or 6 to 7 pounds of bleaching powder per 100 square foot diluted with necessary quantity of water is sprinkled on the whole of the top of the *katchra*, taking care that the sides of the trenches are also carefully treated with the mixture. The operation of applying crude oil is best performed by means of a broom, which is always available on the compost depot. The mixture of crude oil or bleaching powder in water can be prepared in an enamel or iron basin. The same operation is repeated on the 7th or 8th day, i.e. one week after complete processing of refuse. It is generally experienced that bleaching powder does not keep well on storage during the rainy season. Much of its chlorine is lost and the insecticide does not retain its germicidal power. The crude oil treatment is therefore preferred to the bleaching powder. The former is also more economic.

Economics of the treatment.—For a trench of $20 \times 6 \times 3$ feet which would yield five tons of manure, about $1\frac{1}{2}$ gallons of crude oil or 17 pounds of bleaching powder would be required (for two applications as recommended). The cost of these chemicals would be Re. 0-15-0 for crude oil (Re. 0-9-0 per gallon) and Rs. 2-2-0 for bleaching powder (Re. 0-2-0 per pound). Thus the additional cost per ton of manure comes to annas 3 per ton for crude oil and annas 7 per ton for bleaching powder. The insecticides would be used only during the three rainy months of July, August and September, and therefore when the cost of treatment is spread over the whole year's production of manure, it would be very meagre and could be easily recovered from sale proceeds of the manure.

Summary

The use of crude oil and bleaching powder has been observed to be very effective in controlling fly breeding in compost trenches during the monsoon. An application of $1\frac{1}{2}$ pounds of crude oil and 12 pounds of bleaching powder per 100 square feet (in two doses, first one on the 1st day after filling of refuse and second on the 8th day) is recommended. Fly breeding is controlled to the extent of 85 to 90 per cent. The method is very practicable and cheap. Crude oil treatment is preferred to bleaching powder, as the latter deteriorates readily on storage in the monsoon. The former is also cheaper.

ROLE OF FIELD RATS IN THE ENDEMICITY OF PLAGUE IN H.E.H. THE NIZAM'S DOMINIONS

By S. RAGHAVENDER RAO, L.M.S. (Hyd.),
D.T.M. (Bengal), D.P.H., D.Sc. (Calcutta)

Bureau of Epidemiology, Public Health Department,
Hyderabad-Deccan

Introduction and the problem.—Experience of the pandemics of plague shows that at the height of the pandemic many countries which have remained free from plague for a long time are involved, but as the force of the pandemic diminishes plague recedes to certain areas from which it originally started. During the course of this recession, these pandemics leave behind certain endemic centres where the disease smoulders for longer periods due to the more or less suitable conditions prevailing there and, now and then, under more favourable circumstances, shows signs of spreading to the neighbouring areas.

From the recent history as well as from the past records of plague in India, it appears that there are certain such endemic zones of plague here also. The first of these and probably the oldest known is the zone containing certain areas in the sub-montane region of the Himalayas. A second centre appears also to be present in the hilly districts of the Central India plateau and a third in Southern India in the western part of the Mysore State including the districts of Nilgiris, Salem, Coimbatore and Madura in the Madras Presidency. A fourth endemic centre in the plains with which the author is more familiar consists of the districts of Osmanabad, Bidar, parts of Bhir, Gulberga, Atraf-e-Balda and Mahboobnagar in H.E.H. the Nizam's Dominions and the adjoining districts of the Bombay Presidency, viz, Belgaum, Dharwar, Sholapur and Satara.

It will be clear from the above facts that plague in an endemic form has disappeared from a large part of H.E.H. the Nizam's Dominions where it was previously prevalent. However, in some parts the epidemics are still an annual feature and under more favourable circumstances these epidemics sweep over some of the neighbouring districts which have been free from plague for a certain number of years previously.

It is not clear still why certain areas remain as endemic zones of plague while others having similar sanitary environments have got rid of the infection. Connected closely with this epidemiological problem there is another: Where and in what form does the plague infection lurk in an endemic village or town when there are no human cases there or an apparent epizootic?

Considering the lower temperature in the deeper rat-burrows and plenty of food available in the fields, particularly in those localities where groundnut crops are raised, it was thought not improbable that, continuously or at least during the off season, plague epizootics might be

going on among these field rats, and with the onset of the monsoon when some of the burrows in the fields get flooded, these rats might get in contact with the village rats and start a plague epizootic and subsequently an epidemic among the human beings in the village.

As a direct search among the field rats for plague infection particularly in its chronic or attenuated form would be difficult and involve extensive field laboratory arrangements and technique, an indirect approach to the question was decided upon, by treating not individual rat but the whole herd as a unit and by studying the results of the experiment as a mass phenomenon.

If we find on experimentation that rats from the fields surrounding the village are highly resistant to experimental plague infection, all other things being equal and comparable, we may conclude that some form of infection from *Pasteurella pestis* or allied group of organisms is prevalent among the experimented group of field rats which is giving them this amount of resistance to plague infection. On the other hand, if these field rats prove to be highly or more susceptible to plague infection, we may conclude that no plague epizootics have been prevalent for a long time among this group of rats.

To carry out these experiments the village Hassegaon was selected. The village is situated 18° 19' N. and 76° 38' E. and is about 8 miles from Latur, a big trading centre in Osmanabad district. The village is in the middle of the so-called endemic zone and has a population of 1,143 and 319 houses. It has no direct road or rail communication with any of the neighbouring towns but a rough cart tract connects it

zone from the limits of the first zone to the 3rd furlong from the margins of the village. The third zone included all the fields belonging to the village outside the second zone.

Rats were collected from the village and from each of these zones separately. All the rats trapped from the village were *Rattus rattus* and rats caught in the three field zones belonged to the species *Tatera indica*. They were all quarantined for a period of 10 days in specially prepared animal rooms in the compound of the Infectious Diseases Hospital, Latur, and then carried to the Haffkine Institute, Bombay.

All the rats were transported to Bombay at the same time so that the environmental conditions for all the rats remained the same throughout. The food given to all the rats was the same both in Latur and in Bombay. At the Haffkine Institute a rest of 3 days was allowed so that the effects of the railway journey might pass off and the normal conditions obtained again as far as possible. A day previous to the actual testing all rats to be tested were isolated, each rat in a separate cage labelled with the number, species and locality and the zone to which the rat belonged. The standardized infective dose containing a practically constant number of organisms prepared in the Haffkine Institute as described by Sokhey (1936) was used in all the tests. Each infective dose used for these rats contained 450 to 500 *Past. pestis* organisms.

All the rats were inoculated on 22nd May, 1944, and they were kept under observation for a period of 16 days from the date of inoculation. All the rats that died during this period were autopsied, post-mortem signs noted, smears

Summary of the results of the experiments

Species of the rats tested	Locality from which the rats were obtained	Number inoculated with the standard test dose	Number of rats that died of plague	Number dying from causes other than plague	Number that survived the period of observation
<i>Rattus rattus</i> ..	Hassegaon village	22	12	3	7

Control rats					
<i>Rattus rattus</i> ..	Bombay City	10	1	..	9
<i>Rattus norvegicus</i>	Do.	10	2	..	8
<i>Gunomys varius</i>	Do.	10	10

with Latur. The village has been experiencing plague epidemics every year for the last 8 years and every 3 or 4 years for 20 years prior to that.

Methods adopted.—The fields around the village were divided roughly into three zones, the first zone extending from the margin of the village for about 1½ furlongs and the second

from spleen, heart blood and glands examined microscopically, and cause of death ascertained. All those that survived this period were killed and similarly autopsied and results noted. The table gives the summary of the results of these experiments while the statement shown as Appendix 'A' gives the same results in greater details.

The rats from the village (*R. rattus*) showed a high order of resistance to plague infection, 31.8 per cent of them surviving the observation period, while 92.5 per cent of the field rats (*T. indica*) succumbed to infection, showing extreme susceptibility to plague infection, the susceptibility in all the rats from the three zones being almost of the same order.

The resistance showed by the village rats from Hassegaon is of the same order as experienced in other towns having a similar plague history (Sokhey, 1936). Similarly the control rats from the Bombay City showed the same order of resistance as was experienced in several previous experiments carried out at the Haffkine Institute, *Gunomys varius* being highly susceptible and *Rattus rattus* and *Rattus norvegicus* being equally resistant to plague infection.

Discussion

The Indian Plague Research Commission first showed in 1911 that while rats from Madras City, which has been altogether free from epizootic plague, were highly susceptible to a small infecting dose of plague bacilli, rats from other plague-infected towns such as Poona and Bombay exhibited a comparatively high resistance to the same infective dose. Workers in the Haffkine Institute, Bombay, have repeatedly confirmed these findings. In fact, till recently they regularly made use of the high susceptibility of Madras rats for purposes of testing the potency of their plague vaccine and sera.

As to the reason why the resistance of the rats obtained from the areas which were subject to plague epidemic should be higher than that of the rodents from a plague-free area, the Plague Research Commission put forward two possibilities, namely:—

1. That the resistance was acquired as a result of a sub-clinical infection.
2. That it was due to the elimination of highly susceptible strains.

Without arriving at a definite conclusion they rather favoured the latter possibility.

It must, however, be remembered that in the tests carried out in this connection by the Plague Commissioners as well as by other workers the infecting test dose of *Past. pestis* used was such that could not be accurately estimated in regard to the number of organisms or to their virulence.

Again in the case of rats the resistance may be due to an inherent character of the species itself or it may depend upon the place difference for a given species of rats. Our previous experience has shown that acquired immunity cannot entirely be ruled out at least in the case of *Rattus rattus*. At any rate this immunity varies according to the plague history of the place. However, since there is species difference in immunity for rats of the same place as seen by the results of tests on control rats from the City of Bombay (*R. rattus* and *R. norvegicus* are highly resistant and *G. varius*

is extremely susceptible to plague infection), this cannot explain everything.

Our experiments have shown that rats from the fields around the village Hassegaon are extremely susceptible to plague infection. This fact shows that these rodents have not come in contact with plague infection within recent years so as to give rise to the suspicion of their being the cause of the plague endemicity in this area. If these rats had come in contact with plague infection, the rats would have been found more resistant to plague either due to some of them having acquired this resistance by means of sub-clinical doses of infection or the more susceptible strains among them having succumbed to infection leaving only the resistant strains behind.

In view of the fact that intensive fumigation of rat-burrows to eradicate plague infection from the endemic areas is being considered seriously in many places, the question of particular areas to be so dealt with becomes of great importance. If it could be shown that field rats come in contact with plague infection more frequently, not only the rat-burrows in the villages themselves, but those in the fields surrounding the villages also require thorough fumigation. This task becomes enormous and from a financial point of view almost prohibitive. However, our experiments show that, at least as far as Latur area is concerned, we are justified in thinking that field rats do not play any rôle in keeping this area as an endemic plague zone, but it is the village rats and the conditions prevailing in the villages that are chiefly responsible for the persistence of this endemicity. Consequently there is a strong hope that an intensive and frequent fumigation of rat holes in the villages themselves in the affected area will be able to clear the infection much earlier than it might happen in the natural course of events.

Summary and conclusions

From a village in an endemic zone of plague in H.E.H. the Nizam's Dominions rats were collected both from the village as well as from the fields surrounding the village.

All rats caught from the village belonged to the species *Rattus rattus*, while the rats from fields were all of the species *Tatera indica*.

Inoculating all these rats with a standardized dose of plague infection, all field rats showed extreme susceptibility to plague, 92.5 per cent of these dying from acute plague infection; the rats from the village proper showed a fair amount of resistance to plague infection, as nearly 32 per cent of the animals inoculated survived.

It is argued that the fact of the field rats in this area being highly susceptible to plague infection, indicates that these have not been in frequent contact with plague infection and as such could not be the cause of endemicity of plague in this area.

Appendix 'A'

Results of experiments carried out to test the resistance to plague infection from Hassegaon village and its surrounding fields together with rats from Bombay to serve as control

6	<i>Rattus norvegicus</i>	Do.	10	1	2	..	2	2	2	8
7	<i>Gunomys varus</i>	Do.	10	1	1	..	2	1	10

To eradicate plague from the endemic zones it is suggested that intensive and frequent fumigations of rat holes in the villages alone gives a fairly good chance.

I thank the Director, Medical and Public Health Department of H.E.H. the Nizam's Government for giving me the facilities for carrying out this work, Colonel S. S. Sokhey, Director, Haffkine Institute, Parel, Bombay, for allowing me to carry out the immunity tests in the Institute, and Dr. M. Shariff of the Haffkine Institute for the identification of the field rats.

DEVELOPMENT OF HEALTH EDUCATION WORK IN THE UNITED PROVINCES

By A. HAMID, M.B.E., B.S.C., M.B., B.S., D.P.H.
Assistant Director of Public Health, Hygiene Publicity Bureau, U. P.

No apology is needed for writing once more under the above title, as the two previous articles under the title were written before the war (*I.M.G.*, December 1934 and October 1937) and this brief one is intended to link up the past with post-war developments with regard to school medical work.

It has been observed that the finer faculties last to develop are most vulnerable and are liable to disappear first under the effect of major shocks. On this analogy the catastrophe of the war should have affected our programme of school medical work which had already assumed a specialized form in the programme of health education in this province. The war gave us a rude shock as our technical staff was depleted while the skeleton staff had a strenuous time in co-ordinating with the military stations in their anti-epidemic measures and co-operating in their welfare and other activities, such as the War Services Exhibition which was a great show, and the many other smaller, but none the less important, antimalaria exhibitions that were held throughout the province.

But the school medical work continued unabated. The number of towns with a school clinic serving as the centre for the follow-up of defective school children had arisen from five to thirteen just before the war began, all of which have continued to function, and the number of parents and guardians, who have accompanied their wards to the clinics handful at first, has progressively increased very appreciably.

It may be a bold statement that the nutritional condition of school children as judged by the height and weight records has improved under the stress of war. At any rate, the records of average height and weight of school boys, taken

during the last two years of the war, on the whole, show some improvement on those of 1937. And this would not be controverted when it is kept in mind that the records are for that class of population which lives in urban areas and can afford secondary education, so that it could, at the expense of clothing and other amenities, somehow afford meals that, devoid of all extras, become more or less 'square', and thus its diet was less ill-balanced. The current

TABLE I

Average height and weight at various ages of school boys in the United Provinces (1944-45)

54.5	63.5	69.5	117.0
55.0	64.5	70.0	118.75

averages of height and weight for various ages of this class of school-going population are given in table I. We have gone one step further, and have worked out the normal weights for

various heights irrespective of age, as given in table II, as the heights of growing children for the same age vary considerably, and the height factor cannot be ignored in assessing the health of school children. The use of the tables is illustrated by the following example:—

Suppose the age of a boy under examination is 13 years, and he is found to be 58.0 inches in height. The average weight of boys at this age is 79.5 lb. (table I). The average height at this age being 58.5 inches (table I), this boy, although $\frac{1}{2}$ inch below the average for the age, should be considered to be within the range of normal health if his weight is not below 76.75 lb. which is the average weight for boys of 58.0 inches height (table II).

The utility of these tables will be realized after the school health officer has worked on them for sometime, giving due consideration to other factors, besides height and weight, in making an assessment of the nutritional conditions of school children.

Table III shows at a glance the comparative figures for average weights and heights at various ages of boys in the United Provinces at both stages, 1937 and 1944-45, and in Britain and America. The United Provinces figures for heights are not the lowest, but for weights they are, although the weights for 1944-45 show some improvement over those for 1937. Table IV gives the comparative weights for different heights in the United Provinces (1944-45) and in America.

The Famine Enquiry Commission in their final report have deplored that for lack of records no conclusion could be drawn whether there has been a deterioration in nutrition and physique of the people in India during recent years, and it is therefore necessary that records be maintained so that any change in the physical development of the population which may occur in the future may be watched. The efforts of the school medical work made in the United Provinces go to meet the point to some extent and it is hoped that with the development of post-war schemes our medical officers would be able to go further.

A side-issue relating to a feature of dispensing medicine which is commonly neglected, brought to light during the war on account of the necessity of a close scrutiny of stocks in school clinics arising due to the scarcity of quinine, may be mentioned here, as the medical profession has seldom the opportunity to see that their patients are sometimes underdosed. This would happen, for example, when the $\frac{1}{4}$ ounce avoirdupois piece of weight is used for the $\frac{1}{4}$ ounce apothecaries weight of the drug in the prescription, and thus about 40 grains less are dispensed per ounce. Few persons realize that by asking for a dram weight of solids they would get from dealers nearly 27 grains, not 60 grains, of the drug; and the bill of charges for an ounce bottle of the drug would be 16 times the price of a dram, while the contents of the ounce bottle

The nicest way of taking the Natural Vitamins A, C, & D

Haliborange presents Allenburys tasteless and odourless Halibut-Liver Oil, associated with additional vitamin D and concentrated Orange Juice.

Haliborange is an excellent addition to the diet of babies as a precaution against rickets and scurvy. For older children, adolescents, or adults, it is a prophylactic vitamin tonic.

Each teaspoonful of Haliborange contains 1,950 international units of vitamin A, 280 international units of vitamin D, and 7 mg. of Ascorbic Acid (vitamin C)

Haliborange is not available at present but every effort will be made to resume full supplies when conditions permit.

TRANQUILLITY

A calm outlook and freedom from worry and nervous tension are rare in these days. The intense application to war work and consequent mental and physical strain are revealed in widespread headaches and insomnia.

Veganin may well be used to soothe the overwrought nerves, relieve pain and induce sleep. It is a synergistic combination of acetylsalicylic acid, phenacetin and codeine, and is widely known as a dependable and highly effective analgesic, sedative and antipyretic. Veganin is neither toxic nor habit forming.

ACETARSOL VAGINAL COMPOUND

— BOOTS —

VAGINAL ANTISEPTIC

Acetarsol Vaginal Compound—Boots is a preparation containing acetarsol with boric acid and carbohydrate for local application in the treatment of leucorrhoea associated with *Trichomonas vaginalis*.

Clinical results have shown that Acetarsol Vaginal Compound—Boots is superior to vaginal douches, and the patient is spared much inconvenience on account of the ease with which treatment can be carried out.

Supplied in tablets each containing
4 gr. acetarsol.
Bottles of 25 and 100.

grains each out of the ounce bottle. It should at the same time be noted that the pharmacopœial doses which are in avoirdupois weight are denominated to suit the weighment of drugs by the apothecaries weights. For further details the writer's contribution to the correspondence column in the *I.M.G.*, July 1945, may be consulted.

Current Topics

Penicillin for Latent Syphilis

(From the *British Medical Journal*, ii, 9th November, 1946, p. 720)

A TOTAL dosage of 4,000,000 units is recommended. This may be given by means of intramuscular injections each of 30,000 to 40,000 units three-hourly or of 300,000 units twice in the twenty-four hours. Arsenic and bismuth should be employed as well immediately after completing the course of penicillin; the amounts will depend on the results of blood tests. In any case, it would be wise to have the cerebrospinal fluid tested without delay, and adjust continuation treatment according to the findings.

More Potent Penicillin

(From the *Lancet*, ii, 16th November, 1946, p. 738)

AN American company, the Heyden Chemical Corporation, is now producing white crystalline penicillin which, it is said, can be stored dry for three years without refrigeration. According to a B.U.P. report, the potency of this product is the greatest yet developed commercially.

The Storage of Penicillin Preparations

By K. WINTERBOTTOM

(Abstracted from the *Pharmaceutical Journal*, Vol. 156, 8th June, 1946, p. 366)

SUPPLIES of penicillin are now available for civilian use, and this should mean the handling of its preparations by a far greater number of pharmacists than

would be about 40 grains below the dispensers' expectation of 480 grains, with the result that he would not be able to make 48 doses of 10

hitherto. The methods of dispensing, properties and uses of penicillin and its preparations will be well known to those who have studied the numerous articles. However, it was considered that more definite information as to the length of time that the commoner preparations would remain potent would be of practical value. Several preparations were therefore examined under temperature conditions likely to obtain in the ordinary pharmacy. Determinations were carried out upon ointments, solution, and lozenges of penicillin, and it will be convenient to report upon each type of product separately.

ASSAY

The assay process used for the solutions and lozenges was a turbidimetric method. These determinations were carried out at a slightly later date than those on the ointment, and whereas with the ointment the two methods of assay gave results in close agreement, the turbidimetric method seems to give a far lower percentage error, and was chosen for the latter determinations. Even allowing for the margin of error, an occasional obviously high result has been obtained.

OINTMENT

It was decided to carry out the determinations of the ointment at three different storage temperatures, 0°-4°C., 15°C., and 25°C. The first, of course, is that of the refrigerator, 15°C. can be considered to obtain in a cool cellar and 25°C. represents summer heat in the shop.

The ointments used were prepared with the normal 30 per cent Lanette wax SX base. The containers were bakelite-capped jars, the caps being lined with rubber washers, the latter separated from the ointment by a layer of cellophane on the underside. The amount of ointment contained in each jar was 15 gm., and five samples assayed immediately after preparation showed an average figure for penicillin content of 170 units per gm. (calculated). Samples were taken for assay at what were considered suitable intervals, weekly, fortnightly and monthly.

Samples of ointment were also spread on open glass trays, at room temperature, and assayed after 6, 12 and 24 hourly intervals. It was thought that this might give a rough indication of the degree of destruction of penicillin in ointment used upon some exposed part of the body, by airborne and other organisms.

Conclusions.—As will be seen, the percentage loss in the ointment on the open trays is surprisingly slight, being less than 10 per cent in the 24 hours. However, one must conclude that no temperature above that of the refrigerator can be considered suitable for storing the ointment for any but the shortest periods, and even under low temperature conditions there is apparently rapid loss.

SOLUTIONS

The solutions examined were of two strengths:—

(i) A solution of calcium salt containing 2,700 units per mil. and (ii) a dilution of this with saline to give a solution containing 270 units per mil. in sterile physiological saline.

The concentrated calcium salt solution was Seitz filtered, and filled directly into the test containers, using an Ayling filling apparatus, under strictly aseptic conditions. The dilute solutions were similarly prepared by filling into containers holding the previously autoclaved physiological saline solution.

Solutions were stored at the same three temperatures as employed for the ointments. The pH value of the concentrated solution was 6.2, and of the dilute solution, 6.5.

Conclusions.—The diluted saline solutions as prepared have far better keeping properties than the more concentrated solutions, the loss after two weeks being approximately only the same for the dilute solution at 15°C. as for the concentrated solution at 0°C. This of course depends to a great degree upon the impurities present and their concentration. A sterile solution of the strength of the dilute solution employed, can, it appears, be stored at refrigerator temperature

quite safely for two months, and probably for a longer time. Under ordinary conditions of storage, there is apparently little loss in two weeks, and even under fairly warm conditions one week's storage would seem safe. For concentrated solutions, however, the refrigerator is the only safe place, and two weeks would seem to be the safe maximum period.

LOZENGES

The lozenges were prepared under aseptic conditions and dried *in vacuo* over phosphorous pentoxide. The base used was a simple one consisting of glucose with 8 per cent acacia. A lozenge of far more suitable consistency is made with the usual quantities of sucrose, tragacanth, and acacia, but shortage of supplies necessitated using the first formula, and quite a presentable product was obtained. The lozenges were packed into sterile glass tubes which were corked and sealed with cellulose tape. For assay, a lozenge was removed from the tube aseptically, and dissolved in sterile buffer solution.

Conclusions.—This type of lozenge will not remain active for more than two weeks, even when stored in the refrigerator. When storage is below 4°C., there is no loss of potency. Up to four weeks' storage under these conditions the loss was approximately one-third, while at the end of two months the loss was two-thirds of the original potency. At 15°C., the lozenges were almost without activity in two weeks.

B. A. L. as Antidote to Mercury

(From the *Lancet*, ii, 16th November, 1946, p. 738)

According to the British United Press, a two-year-old boy in Los Angeles who swallowed three tablets of bichloride of mercury has recovered completely owing to the administration of British anti-lewisite.

The Treatment of Asthma with Rectal Suppositories of Aminophylline and Sodium Pentobarbital

By S. J. PRIGAL *et al.*

(Abstracted from the *Journal of Allergy*, Vol. 17, May 1946, p. 172)

1. AMINOPHYLLINE suppositories gave relief to 38 of 47 patients (80.8 per cent) during an attack of asthma. Aminophylline in combination with pentobarbital sodium was more effective, relieving 44 of 47 patients (93.5 per cent).

2. Where the asthma responded to the suppository, it required about one-half the time with the combination, in most cases, as compared with plain aminophylline.

3. The combination of aminophylline and pentobarbital sodium helped 44 of 47 patients (93.5 per cent) in reducing the frequency and severity of attacks. Aminophylline alone was helpful in 25 of 45 patients (55.5 per cent). The suppositories were given twice daily.

4. No untoward reactions to the suppositories were observed in this series. Some complaints, such as itching, burning or diarrhoea, were reported. Most of these complaints were relieved by lubricating the suppositories with nupercainal ointment.

5. The suppositories may be helpful in the treatment of infants and children due to convenience of administration and rapid action.

6. The suppositories of aminophylline and pentobarbital sodium are effective in mild and moderate cases of asthma. A patient with a severe attack must be given the aminophylline intravenously.

7. Three cardiac patients in this series responded well, probably because of the beneficial effects of aminophylline on the coronaries and due to its diuretic action.

Benzhydryl Ether Hydrochloride (Benadryl) in the Symptomatic Treatment of Allergy

By E. SCHWARTZ

and

L. LEVIN

(Abstracted from the *New York State Journal of Medicine*, Vol. 46, 1st June, 1946, p. 1233)

1. A group of 50 patients with various forms of allergy were treated with Benadryl.

2. Symptomatic relief occurred in 8 of 20 cases (40 per cent) of asthma; in 6 of 10 cases (60 per cent) of vasomotor rhinitis; in 4 of 5 cases (80 per cent) of chronic urticaria; in 8 of 8 cases (100 per cent) of acute urticaria; and in 3 of 7 cases (43 per cent) of miscellaneous allergies.

3. The majority of the patients who obtained relief from Benadryl reported benefit within one hour after administration. Symptomatic relief was palliative.

4. Side reactions occurred in 30 patients, or 60 per cent of the entire group. In 26 patients the side reactions disappeared gradually even while continuing the drug on the initial dosage schedule of 50 mg. every four hours. Four patients stopped the use of Benadryl because of severe side reactions.

5. It is concluded that Benadryl was an effective drug in the symptomatic relief in 29 of the 50 (58 per cent) allergic patients.

New Mercurial Antiseptic

(From the *Pharmaceutical Journal*, Vol. 156, 29th June, 1946, p. 416)

An organic mercury compound, 2-acetoxy-mercuri-4-diisobutylphenol, known under the trade name 'Merbak', has been tested for bactericidal activity by Heinemann and Blanchard (*J. Amer. Pharm. Assoc.*, 1946, 35, 54). It was found to be active against *S. aureus*, *E. typhosa*, *E. coli str. haemolyticus* and *Dip. pneumoniae* in concentrations which varied from 1 in 10,000 to 1 in 30,000 (*Dip. pneumoniae*), against *Ps. aeruginosa*, 1 in 3,000, all at 20°C. It was active in serum broths. Moreover, it proved to be fungicidal against *Tr. rosaceum* in a dilution of 1 in 1,000, and inhibited the growth of this fungus in a dilution of 1 in 30,000. Its toxicity to rats and chick embryos is said to be low, and it is claimed to be non-irritating to the skin.

A New Antimalarial

(From the *Pharmaceutical Journal*, Vol. 156, 29th June, 1946, p. 416)

For the past two years the U.S. Board for the Coordination of Malarial Studies have been examining the effects of a new antimalarial SN 7618 on animals and man. Their report now published (*J. Amer. Med. Assoc.*, 1946, 130, 1069), shows that chemically the substance is 7-chloro-4-(4-diethyl-amino-1-methyl butyl-acino) quinoline. It was found that SN 7618 is highly active against the erythrocytic forms of *P. vivax* and *Plasmodium falciparum* but will not prevent relapse. Its activity is said to be approximately three times that of mepacrine. In suppressive therapy a dose of 0.3 gm. given on the same day in each week is recommended; in the treatment of an acute attack an initial dose of 0.6 gm. is followed by 0.3 gm. after six to eight hours and a single dose of 0.3 gm. on each of two consecutive days.

Bacitracin : A New Antibiotic

(From the *Pharmaceutical Journal*, Vol. 156, 29th June, 1946, p. 416)

A NEW antibiotic, 'Bacitracin', has been produced from the strain of the *B. subtilis* group of organisms by B. A. Johnson, H. Anker and F. L. Meleney (*Science*,

1945, 102, 376). *In vitro*, it is chiefly active against gram-positive organisms, but it also inhibits the growth of gonococci and meningococci. It is effective against haemolytic streptococcal infections in mice and against gas gangrene infections in guinea-pigs. 'Bacitracin' is a neutral, water soluble, non-toxic substance; it is relatively heat-stable, as no significant loss of activity was noted after heating at 100°C. for 15 minutes. When tested against gas-gangrene organisms using guinea-pigs, 80 per cent of the animals were alive and well two weeks later, whereas all the control animals were dead within 12 hours. It has also been shown to be effective against haemolytic streptococci in mice. Used locally in a small number of human cases against staphylococci and haemolytic streptococci, 'Bacitracin' gave satisfactory responses comparable to the action of penicillin.

A Sermon in Wood

(Abstracted from the *Canadian Medical Association Journal*, Vol. 55, July 1946, p. 79)

THERE is a door in the Hamilton (Canada) Museum from an old house in that city. The old house, demolished in 1894, had been the residence of a doctor Case for so many years—and of his father and grandfather—that the door in question had become worn in a fashion which to Sir William Osler, an old friend of the Case family and one who always called to pay his respects when in that part of Canada, was a sermon in wood, so to speak. Sir William wrote an editorial about this symbolic door with the title of 'Doctors' Signs' which was published in the *Canadian Medical and Surgical Journal* (12, 312, December 1883). This is what he said about the door's symbolism:

'Happy is the man whose reputation is such or whose local habitation is so well known that he needs no sign! This is sometimes the case in country places and small towns, not often in cities. We know of one such in a prosperous Canadian city. Grandfather, father and son have been in "the old stand" so long that to the inhabitants of the locality the doctor's house is amongst the things which have always been. The patients' entrance is in a side street and a small porch protects the visitor. The steps are well worn and the native grain is everywhere visible in the wooden surroundings. There is neither bell nor knocker and the door presents interesting and, so far as we know, unique evidences that votaries to this Aesculapian shrine have not been lacking. On the panels at different heights are three well-worn places where the knuckles of successive generations of callers have rapped and rapped and rapped. The lowest of the three, about three feet from the floor, represents the work of "tiny Tim" and "little Nell", so often the messengers in poorer families. Higher up and of less extent is a second depression where "Bub" and "Sis" have pounded, and highest of all, in the upper panel a wider area where the firmer fists of the fathers and brothers have as the years rolled on worn away the wood to nearly half its thickness. Such a testimony to the esteem and faithfulness of successive generations of patients is worthy of preservation.'

Basal Body Temperature Graphs as an Index to Ovulation

(From the *Medical Journal of Australia*, Vol. 1, 4th May, 1946, p. 634)

PENDLETON TOMPKINS (*The Journal of the Obstetrics and Gynaecology of the British Empire*, June 1945) advocates the use of daily temperature readings as a method of ascertaining the time of ovulation. He maintains that the basal temperature in women consistently shows a drop followed by a rise about fourteen days before the onset of menstruation. The rise is then maintained until menstruation begins. The author recommends this method as the simplest and most accurate way of timing ovulation for an individual

woman. To obtain a basal temperature reading it is suggested that it be taken *per rectum* in bed before rising each morning. The patient is instructed to keep a chart of the daily readings, noting any intervening conditions, such as sore throat, which may cause a rise in temperature. Using such charts as an index of ovulation, the author was able to predict the time of maximal fertility for those who wish to conceive. Obviously this occurs immediately after the temperature shift takes place. These charts are equally valuable for ascertaining the 'unsafe' period for those who do not use contraceptives, but have no wish to conceive, especially when there is irregularity of periods. When pregnancy supervenes the ovulatory temperature rise is uniformly maintained, so that this observation, coupled with amenorrhoea, is a suggestive sign of early pregnancy—the poor man's Friedman test'. Other uses to which these charts may be put include the evaluation of treatment intended to stimulate ovulation, as an aid in securing biopsies in the pre-ovulatory or post-ovulatory phases of the endometrium, in studying the effectiveness of contraceptives, and as a means of investigating some types of irregular uterine bleeding.

An Experiment in the Rationing of Food

(Abstracted from the *Medical Journal of Australia*, Vol. 2, 27th July, 1946, p. 134)

In September 1939 Professor R. A. McCance informed the Medical Research Council that he proposed with Miss E. M. Widdowson to study the effect on human beings of a diet (a) which might be available under conditions of war and (b) at which the authorities ought to aim as a minimum even if the country was in dire straits as a result of the enemy blockade. The planning of the work 'involved some prophecy as to what might happen with regard to feeding arrangements in the war'. The prophecy tallied fairly closely with reality.

Eight persons were the subject of the experiment. After a preliminary week of taking ordinary food they were subjected to the experimental diets for periods varying from two weeks to three and a half months. During the preliminary period of the experiment and in certain cases during the post-experimental weeks the subjects weighed all the food that they ate, noted how they enjoyed it, what effects it had upon them and whether they felt it. In the preliminary period and during certain of the subsequent weeks six of the subjects collected their excreta for investigation and for chemical analysis. Laboratory tests of nutritional fitness were carried out from time to time on the long-term subjects and towards the end of the experiment field tests consisting of mountaineering and of long-distance cycling were applied. The diet for the experiment consisted of unrationed and of rationed elements. The unrationed foods were potatoes, green and root vegetables and bread made from flour containing 92 per cent of the original wheat and fortified with calcium carbonate. The rationed elements for each week comprised 16 ounces of meat, fish, poultry or rabbit; four ounces of cheese; four ounces of margarine (this was the total fat allowed); five ounces of sugar including jam, marmalade *et cetera*; two ounces of oatmeal; four ounces of rice; ten ounces of pulse; one egg; 35 ounces of whole milk; six ounces of fruit. These amounts were a good deal less than those allowed in the war-time rations. The war-time rations included each week eight ounces of fat, eight ounces of sugar and some jam; from two pints up to unrestricted amounts of milk were allowed with some dried separated milk, the amount of meat was what could be obtained for one shilling and two pence, together with three to six ounces of bacon *plus* unrationed fish, poultry and rabbits. The war-time allowance of cheese was four ounces and later three ounces of cheese. The degree, form and extent of the adaptation to the experimental diet demanded of each

subject varied with the diet to which he had previously been accustomed. All who were tested for three months made satisfactory adjustments; one person whose physical adaptation was good was apprehensive and worried and was regarded as having failed in psychological adaptation. The diets themselves are described as containing quite enough protein, though they were inevitably low in animal protein. They contained very little fat but correspondingly large amounts of carbohydrate, most of which was in the form of starch. The diets provided as much calcium as normal diets; plenty of phosphorus and other minerals and much more vitamin B₁ and vitamin C than most English diets. A study of excretions showed that the urine of each subject contained about the same amounts of magnesium and phosphorus as before. The urine contained less calcium, suggesting that less was absorbed, and this was at first attributed to a vitamin D deficiency, but it was found impossible to alter the urinary faecal ratios by giving moderate doses of calciferol. Once the subjects had adjusted themselves they were satisfied and content; they liked the food, approached it with gusto and did not find it monotonous. The health of the subjects was particularly good all the time that they were living on this restricted dietary, and at the end of three months they were able to take prolonged and severe physical exercise without undue fatigue. The 'inevitable' conclusion was that once an adult had become accustomed to the diet, it was satisfactory for all ordinary purposes.

The result of this investigation must have been surprising to those in war-time Britain who had to do with the food supplies during the stressful days of the war. It was recognized that if restrictions as severe as those of the investigation had to be faced, the problem would be how to effect their introduction and have them accepted by the people. One or two prominent facts and conclusions may be mentioned. First of all, if the food of the people is rationed in certain directions, they will certainly try to keep up their calories from unrationed foods. Again it is pointed out that since the three staples, wholemeal bread, potatoes and green vegetables, were of the greatest value, not only should everything be done to leave them unrationed in a crisis, but rich and poor should alike be able to command them. Perhaps the most important statement in regard to food itself is that for emergency rations only flour containing 92 per cent of the original wheat should be considered. Again if a milk shortage is envisaged at any time, calcium should be added to the bread.

This work is likely to have results in other spheres than those of war. This is shown by the observation that the authors of the report could see no justification for the enormous amounts of meat in the rations of the British soldier; they considered that troops, at least in Britain, would be just as well served with bread made from a lightly milled flour, more potatoes if necessary, and less meat. Had such views been published during the war, they would have received a warm welcome from many civilians, particularly from harassed housewives. This work may also be useful to those who plan food relief for countries affected by the present world food shortage.

Incidence of Leukemia in Radiologists

By U. HELMUTH

(From the *New England Journal of Medicine*, Vol. 234, 10th January, 1946, p. 45. As abstracted in the *International Medical Digest*, Vol. 48, April 1946, p. 199)

'EXPOSURE to x-rays has for some time been regarded as a possible cause of leukemia. This belief is based in part on results obtained by experimental exposure of animals to x-rays and in part on several reports of cases of leukemia occurring in workers exposed to radiation.'

Since the majority of physicians are not subject to exposure to radiation it seems that a comparison of the

incidence of leukemia among radiologists and that among other physicians should give some conclusive results. 'The present report is based on a statistical study of deaths of physicians reported in the Journal of the American Medical Association during the 10-year period 1935 to 1944.

'It must be admitted that the results cannot be perfect, first, because the cause of death is not given in about 25 per cent of the obituary notices, and second, because in an even greater number there is no indication of possible x-ray exposure. For example, some of the physicians not listed as radiologists but dying from leukemia may have been exposed to radiation—the case reported at the end of this article is of this type—which would increase the incidence of leukemia in the exposed group. Conversely, some unexposed physicians, the cause of whose death is not given, may have died of leukemia, which would increase the incidence in this group. It is not unreasonable, therefore, to assume a tendency of the various unknown opposing factors to balance each other. At any rate, if the difference between the two groups is sufficiently large, it should not be significantly affected by these discrepancies.

'From 1935 to 1944, inclusive, the deaths of 34,626 physicians were recorded in the Journal of the American Medical Association. Two hundred and five of these men were listed as radiologists. The total stated number of deaths from leukemia is 158. Eight of these occurred among the 205 radiologists, giving a percentage of 3.9; 150 were among the 34,421 physicians not listed as radiologists, a percentage of 0.44. Therefore, those known to have been exposed to radiation had an incidence of leukemia more than eight times as great as those who are not listed as radiologists. Although this difference may be affected somewhat in either direction by the previously discussed lack of complete information, it seems too great to be wiped out or to be significantly modified.

'This statistical study which supplies substantial evidence that exposure to radiation is a potential cause of leukemia was suggested by the occurrence of this disease in a physician who had repeatedly been exposed to radiation over a long period of time. The following data summarize the findings in this case:—

R. J., a 51-year-old dermatologist, had for several years failed to take precautions against exposure to radiation that he used for treating his patients. Symptomatically his illness began in the fall of 1941, the major complaint consisting of pain in various parts of the body, especially in the chest. It became quite severe during a period of 6 weeks and was aggravated by motion and deep respiration. Slight fever (99.2°F.) was present. The skin was pale and suggested anaemia, which was confirmed by examination of the blood, the red cell count being 2,610,000 and the haemoglobin 45 per cent. Leukopenia was present, the number of leukocytes varying between 1,500 and 5,540 per cu. mm. and the percentage of neutrophils between 4 and 54. The lymphocytes, largely normal in appearance, were the most numerous leukocytes in the majority of smears. At times occasional immature cells of the lymphoblastic type were found. The leukopenic blood picture persisted essentially unchanged for 6 months, when the total number of leukocytes began to increase and reached a maximum of 163,200 within 2 weeks, with a differential count typical of lymphatic leukemia. The patient died on 20th August, 1942, approximately 9 months after the onset of symptoms. Autopsy confirmed the diagnosis of lymphatic leukemia.

'This case is intentionally omitted from the group of 8 cases of leukemia occurring in radiologists, because the notice of this patient's death gave no indication that he had been exposed to radiation. If his case were included in the radiologic group the percentage of leukemic deaths therein would be increased to 4.3, and the percentage in the non-radiologic group, in which his case was included, would be slightly lower, thus accentuating the difference between them.

'The fact that the patient was a dermatologist suggested a separate estimation of the incidence of

leukemia in physicians practising that specialty. During the 10 years covered by the study 60 physicians listed as dermatologists died. Two of them, including the one reported in this article died of leukemia, giving a percentage of 3.3. This approaches the incidence in the radiologic group, but the number of cases is too small to be of statistical significance.'

The Differential Diagnosis between Renal Colic and Acute Appendicitis

By H. BAILEY

(Abstracted from the *Urologic and Cutaneous Review*, Vol. 50, July 1946, p. 398)

Woe betide a patient with gangrenous appendicitis who passes blood in the urine! Until it is better known that an inflamed appendix lying in juxtaposition to the ureter can give rise to ureteritis that causes haematuria, lives will be lost. In my experience, when blood is found in the urine, the practitioner invariably rules out appendicitis, and not infrequently the consultant aids and abets him in treating the patient for 'pyelitis'. In no less than 80 per cent of cases falling into this group, the inflamed appendix occupies a retrocaecal position.

Directly connected with this outstanding example of misleading symptomatology is the anatomical variation where an inflamed appendix is resting upon, or becomes attached to the urinary bladder. It will be readily appreciated that in such circumstances the symptoms produced are wont to be predominantly urinary, although in this instance haematuria is usually late and rare. So it comes about that numbers of unfortunate individuals presenting symptoms that direct attention to the urinary organs, are denied the advantages of early extirpation of an inflamed appendix, a boon accorded to their brethren presenting more typical clinical features.

Paradoxically, because a stone in the ureter often fails to produce either haematuria or increased frequency, but only colic, numbers of patients harbouring a stone in the right ureter bear the sear of a recent appendicectomy.

Better urgent pre-operative investigation is sorely needed.—In most instances of acute right-sided abdominal pain with urinary symptoms, a concrete pre-operative diagnosis is possible. In urban communities where the aid of radiography and kindred scientific investigations are so freely restored to, it is unforgivable that an opportunity for their employment of such vital importance should be allowed to flit by. Excretory pyelography is of proven value in eliminating renal colic when acute appendicitis is suspected.

Helge Wulff collected from the records of the surgical division of the University of Lund, Sweden, nearly 500 examples of acute right-sided abdominal pain where the symptoms were mainly urinary. Every patient in the series was subjected to urgent excretory pyelography. Those whose right kidney and ureter visualized normally were hurried to the operating theatre. No less than fifty-nine of these patients were found at operation to have a gangrenous appendix lying near the right ureter. As a result of this study, Wulff comes to the following most important practical conclusion: *If the differentiation between early acute appendicitis and renal colic is at stake, urgent excretory pyelography should be undertaken. When the pyelogram shows a normal outline, appendicectomy should be performed forthwith.*

In a number of instances, where I could not make up my mind as to whether a patient was suffering from renal colic or early acute appendicitis, I have performed urgent cystoscopy and, when facilities existed, have invoked the aid of radiology as well. With a catheterizing cystoscope alone one can often prove that the patient is suffering from a lesion of the right ureter. On several occasions after a ureteric catheter has been passed up the right ureter, a brisk dripping

of limpid urine through the lumen of the catheter has resulted in immediate amelioration of symptoms.

The Choice of Drugs in Diseases of the Chest

By N. C. OSWALD

and

J. W. SPENCE

(Abstracted from the *Pharmaceutical Journal*, Vol. 157, 24th August, 1946, p. 121)

IN recent years, great advances have been made in the management of the more serious diseases of the chest. The introduction and development of collapse therapy, postural drainage, breathing exercises, the sulphonamides and penicillin have tended to lessen the importance of non-specific pharmacological remedies. However, bronchitis and inflammatory conditions of the throat remain as the commonest affections of the respiratory tract and require treatment by expectorants, analgesics and sedatives.

ACUTE BRONCHITIS

In the early stages of acute bronchitis, when the bronchial mucosa is dry and oedematous and coughing is painful, a mixture containing a sedative and a mild expectorant is given, the following being a very popular remedy which, under different titles, is to be found in many hospital pharmacopœias :—

Camphorated tincture of opium ..	30 minims
Oxymel of squill ..	30 minims
Emulsion of chloroform, B.P.C.	5 minims
Infusion of gentian ..	to 1 fluid ounce

The use of small doses of morphine at this stage is fully justified, the cough centre being depressed by a smaller dose of this drug than is necessary to produce sleep. The squill and camphor in the mixture help to relieve the tension in the acutely inflamed mucosa and promote secretion, thus easing the pain.

Should pain be a prominent feature in the early stages of acute bronchitis, the inhalation of tincture of benzoin from a steam kettle may give considerable relief. In practice, the compound tincture of benzoin has no advantage over the less expensive simpler one of the Codex, which is usefully employed in the proportion of one fluid drachm to a pint of hot water.

When the acute stage is past, and the sputum becomes mucopurulent or purulent, more energetic measures are taken to promote expectoration. The most uniformly efficient expectorant is a 'hot water mixture' such as the following :—

Sodium bicarbonate ..	20 grains
Sodium chloride ..	3 grains
Emulsion of chloroform, B.P.C.	5 minims
Distilled water ..	to 1 fluid ounce

An ounce of hot water is added to an ounce of the mixture, and this is sipped and drunk as hot as possible. This remedy is most effective when taken on waking in the morning, and usually breaks up a tenacious sputum in about half an hour.

CHRONIC BRONCHITIS

In chronic bronchitis, the 'hot water mixture' is equally efficient in promoting expectoration. Of the well-known expectorant drugs and their preparations, perhaps ammonium carbonate (3 grains), tincture of ipecacuanha (20 minims), potassium iodide (3 grains), tincture of squill (20 minims) are the best; a mixture contains not more than one of these substances and the one selected is used in the dosage indicated. When cough is troublesome camphorated tincture of opium is added. A mixture such as the following, which combines a mild additional diaphoretic effect with reasonable palatability, has been found suitable :—

Tincture of squill ..	20 minims
Camphorated tincture of opium ..	30 minims
Spirit of nitrous ether ..	30 minims
Dilute solution of ammonium acetate.	120 minims

Camphor water .. to 1 fluid ounce

Alternatively a linctus may be used :—

Camphorated tincture of opium ..	20 minims
Syrup of squill ..	20 minims
Syrup of tolu ..	to 1 fluid drachm

BRONCHIAL SPASM

When bronchial spasm is present, inhalations of tincture of benzoin may give much relief provided the patient is not too ill; in severe cases a feeling of suffocation may be produced. Such inhalations should be restricted to patients who are confined to bed. As a routine remedy for bronchitis with asthma, the following is used :—

Potassium iodide ..	3 grains
Tincture of stramonium ..	15 minims
Liquid extract of liquorice ..	20 minims
Emulsion of chloroform, B.P.C.	5 minims
Distilled water ..	to 1 fluid ounce

BRONCHIECTASIS

In bronchiectasis, expectorants are of little value; a mixture containing potassium iodide (in 3-grain doses) may serve to promote expectoration, but the medical treatment is essentially postural.

TUBERCULOSIS

In tuberculosis, expectorants are rarely used; if a specimen of sputum is particularly needed for pathological investigation, one of the expectorants already mentioned may be tried, but potassium iodide should be avoided.

PAINFUL CONDITIONS OF THE THROAT

For painful conditions of the throat, a variety of measures may be adopted. Painting of the throat with Mandl's paint or the use of an aspirin gargle is effective in the milder cases, or a simple linctus may be given. In severe conditions, such as tuberculous laryngitis or carcinoma, a linctus such as the following is used :—

Codeine phosphate ..	1/10 grain
Citric acid ..	1 grain
Glycerine ..	20 minims
Syrup ..	20 minims
Emulsion of chloroform, B.P.C.	2 minims
Distilled water ..	to 1 fluid drachm

or

Diamorphine hydrochloride ..	1/16 grain
Glycerine ..	10 minims
Syrup of tar, B.P.C. ..	to 1 fluid drachm

Amongst the lozenges, the time-honoured Brompton variety, or a tablet containing menthol have stood the test of time. The formulæ of these are as follows :—

Extract of liquorice ..	3 grains
Oil of anise ..	1 minim
Lozenge of acacia, B.H.P. in each lozenge.	10 grains
Menthol ..	1 grain
Fruit basis, B.P.C. in each lozenge	25 grains

The official Brompton lozenges are coloured black by the addition of charcoal.

Of the inhalants, the following (5-8 drops on a Burney Yeo inhaler) is very soothing :—

Oil of cassia, B.P.C. ..	} of each equal parts
Oil of eucalyptus ..	
Oil of Siberian fir ..	
Creosote ..	

With the passage of years, many of the popular remedies of the recent past have fallen into disrepute; mustard leaves, mustard plasters and linseed poultices have almost disappeared; kaolin poultices are no longer used for the relief of 'Congestion of the lungs'. Such benefit as might have accrued for increased vascularity

is more than outweighed by the disadvantages of discomfort, soreness of the skin, and constriction of the chest by tight binders. Kaolin is, however, useful in the relief of pain in pleurisy.

Medicolegal

Compensation Court

Rowbottom v. Shaw, Savill and Albion Company Limited

Coronary Disease and Myocardial Infarction

(From the *New Zealand Medical Journal*, Vol. 45, June 1946, p. 181)

THE plaintiff was a waterside worker, 46 years of age. On 5th May, 1943, he claimed that he sustained an accident in the course of his employment when he was helping to drag a tray along so as to place it in the chest. The pain became worse as he kept on working, but when he spelled between the loadings of the cargo the pain eased up a little. He continued working during the morning until the lunch hour and the pain, which had almost disappeared during that period, returned again with increased severity as soon as he started work. He stopped work at 3 p.m. and took a tram to consult a doctor, but not being successful, he returned to his home at Khandallah. His home was up a considerable hill and on that occasion instead of taking seven or eight minutes to walk from the station to his home it took him 1½ hours. Some time later he was admitted to the hospital and it was there found that he had been experiencing pain on effort for the previous five months.

The case was regarded in the hospital as being one of coronary thrombosis or more properly myocardial infarction. After a period of six or seven weeks in the hospital the patient was discharged with an admonition that he should not thereafter engage in heavy work.

For the plaintiff medical evidence was called indicating that as a result of the effort Rowbottom made, and especially the repeated effort, the heart was called upon to do more work than could be compensated for by his coronary blood flow. Under these circumstances of coronary insufficiency infarction of the heart muscles was likely to occur. This was the explanation of the infarction which was offered by the medical witness for the plaintiff. For the defendant Company the medical witnesses held that the infarct was the result of coronary atheroma followed by coronary occlusion and probably coronary thrombosis, a gradual and apparent insidious disorder occluding the arteries of the heart and that such a condition was not connected with effort on the heart and that such a condition was not connected with effort on the plaintiff's part.

The trial judge (Sir Archibald Blair) said in his judgment that the real dispute or divergence in the views of the experts was this: One held that the plaintiff had coronary insufficiency precipitated by some factor that increased the work of the heart or reduced the ordinary blood flow thus causing an infarction of the heart muscle without the presence of coronary thrombosis. The inciting factor of such infarction was suggested as being great emotion or effort. The other held that the obstruction in the artery which interfered with the blood supply to the plaintiff's heart and caused the infarction was due to thrombosis, an insidious disease of the arteries which is not related to external factors and that effort played no part in causing it. After reviewing the medical evidence the learned judge said that he had been referred to a

previous case—*Charlton v. Makara County Council*—which he had been invited to regard as being a precedent on which the present case could be decided. In his judgment however he said that when a compensation case was decided on questions of fact then the decision of a judge on such a question is of little help in deciding another case depending also on questions of fact. He then referred to two circumstances in the history of the case which he thought were different in material respects. One marked distinction which he referred to was that in Rowbottom's case the plaintiff had had several attacks of angina during the four or five months before the alleged accident and also that it could not be successfully claimed that the effort he spoke of as having occurred on 5th May, 1943, was one of 'abnormal severity'. The only effort deposed to on the date of the alleged accident was that related to his ordinary normal work and furthermore the pain that he felt on that date did not disable him altogether because he continued work with occasional spells, then had a spell for lunch and resumed again in the afternoon working for another two hours until he found himself unable any further to proceed. Charlton on the other hand had no previous history of heart trouble and was totally incapacitated from the moment of the alleged accident. The judgment held that the plaintiff's claim must fail.

Because of the interest which compensation cases involving coronary disease have excited in the minds of physicians and pathologists the foregoing note is submitted. The judgment is reported in full in the *New Zealand Law Reports*.

Infamous Conduct in a Professional Respect : Epstein v. Medical Board of Victoria

(From the *New Zealand Medical Journal*, Vol. 45, June 1946, p. 179)

A MEDICAL practitioner of Victoria, Zigmund Epstein, had his name erased from the medical register of Victoria by the Medical Board of that State on the ground that he had been guilty of infamous conduct in a professional respect in that he himself anaesthetized a patient and then removed the patient's tonsils by blunt finger dissection and at the end of the operation allowed the patient to be removed from the operating theatre without properly controlling the hæmorrhage.

There is provision for appeal to the Supreme Court in the Victorian Medical Act and the judgment of the Court (Mr. Justice Lowe) is set out in the *Victorian Law Reports* (1945, V.L.R., 309).

In his review of the circumstances the judge said that it was open to the Board to find that the appellant performed the operation without an anaesthetist which in itself was a dangerous proceeding and called for the exercise of the greatest care in the performance of the operation; that the appellant then operated in a crude and unskilful manner by the method of blunt finger dissection; that there was an unusual amount of bleeding; that the appellant's attention was called to that fact in the operating theatre at the end of the operation and he made no attempt to stop the bleeding or to see that anyone else did and as a result the patient's life was endangered and when he did give belated attention to the child he wrongly diagnosed the condition as one of shock: that his whole conduct showed a lack of concern for the welfare of his patient and that for all these reasons his conduct amounted to infamous conduct.

The learned judge said that if the matter had rested there and he was limited to that evidence he would not have disturbed the decision of the Board. The Court had before it however affidavits from several medical experts of high standing and from these it would appear that the method used by the appellant was orthodox and indeed was extensively used in public hospitals in Victoria and furthermore that it was easy to mistake a condition of loss of blood for shock. These affidavits also expressed the views that to operate without an anaesthetist was not improper in the

circumstances. This evidence seemed to the learned judge to vitally change his view of the nature of the appellant's conduct and to raise some doubt as to whether the appellant's conduct did in fact amount to infamous conduct. The state of doubt created was such that the learned judge held that the charge was not proved and ordered the appellant doctor's name to be restored to the medical register.

The appellant was not a British graduate. According to the medical register in Victoria he holds the qualification of M.D. (Rome), 1937.

Dying Declaration

Rex v. Ivan Manfred Kahu

(From the *New Zealand Medical Journal*, Vol. 45, June 1946, p. 180)

IVAN MANFRED KAHU, a young Maori, was indicted at the Supreme Court of New Zealand at Hamilton in February 1946 on two counts of murder, the first in relation to his wife and the second in respect of one Amundsen.

The prosecution alleged that at approximately 4 p.m. on 8th December, 1945, the prisoner murdered Amundsen by smashing his head in with blows of an ordinary claw hammer and that at about the same time the prisoner also murdered his wife by cutting her throat three times with a safety razor blade and also bashing her head in with the same claw hammer. The evidence did not disclose which of these two persons was first attacked. Mrs. Kahu was found in a dangerously wounded condition near the front door of a neighbour's house. The victims were removed to the Taumarunui Hospital where the accused's wife was operated on within a short time after her admission. Her throat had been cut by means of a safety razor blade right across from the sternomastoid muscle to the other, the windpipe being completely severed. Extensive bleeding had taken place from these wounds. In addition extensive injuries had been inflicted on her skull and brain, but notwithstanding the injuries she was not in a comatose condition when she was first seen by a neighbour or when she was first admitted to the hospital.

The Crown tendered two items of evidence submitted as dying declarations made by Mrs. Kahu. Amundsen's father found his son grievously injured lying stretched out on the verandah of his house. He went at once to get the police and this involved passing the house of a neighbour named Walsh. Squatting in the doorway of this house and holding on to the sides of the doorway was Mrs. Kahu with her head battered in and her throat cut. Amundsen asked her: 'Did Kahu do this?' and she nodded her head. He then asked her if she could speak and she shook her head. Amundsen then left to get assistance. That incident relating to Amundsen, Senr., was tendered as evidence admissible as a dying declaration by Mrs. Kahu.

Shortly after Mrs. Kahu's admission to the Taumarunui Hospital and whilst being prepared for operation by Sister Turner of the hospital staff Mrs. Kahu indicated to the sister that she wished to write and made a sign of writing on the front of the sister's uniform. Owing to her throat injuries it was impossible for Mrs. Kahu to speak. The sister then handed Mrs. Kahu pen and paper and she thereupon wrote on it as follows:—

'I'm cold
'My husband cut my
'throat while he was
'interviewing me in our house
'in Mananui
'please pull the bed
'clothes over my
'shoulders.
'Where's the doctor.'

This document was also tendered in evidence as a dying declaration.

Following the operation to suture up the severed parts of the throat and also to clear up the injury

to her skull and brain Mrs. Kahu lived for thirty-two hours.

Evidence on the medical aspects of the case was taken in Chambers from two doctors. The Presiding Judge Sir Archibald Blair after hearing this evidence and hearing argument by counsel reviewed the basis of the practice as to the admission of dying declarations made in the absence of the accused. Such declarations are admissible only upon the trial of a person accused of the murder or man-slaughter of the person making the statement. There is a further condition, viz, that the statement can be admitted in such cases only when made under such circumstances as in effect to give it the equivalent of the sanctity of an oath.

The point that must be enquired into is whether the mental condition of the declarant at the time that the declaration was made was that of hopeless expectation of death. That is a question of fact and in most of the reported cases the declarant has been able to speak. The difficulty in this case is to ascertain whether the person making the declaration absolutely believes that he or she is about to die and as it has been put in the cases the question is whether the declarant has a settled hopeless expectation of death. The learned judge reviewed some previous decisions on this matter and said that he had not been referred to any cases where the condition of the declarant's mind could be inferred from the serious nature of the injuries. He could see no reason in principle why the desperate nature of the injuries of the declarant could not alone be sufficient to enable it to be inferred that he or she had a settled hopeless expectation of death.

After reviewing the medical evidence on this point the learned judge went on to say that he attached importance to the fact that the injured person went through a remarkable mental and physical effort in making the written statement. She would not have done that if she had thought she was going to recover. His view was that as a pure question of fact the deceased's statement voluntarily made to Sister Turner was made with the imminent shadow of death upon her and with the solemnity which that connotes. He therefore held that it was admissible as a dying declaration.

In regard to the earlier statement made by signs to Amundsen, Senr., the learned judge held that that also was admissible as a dying declaration. Nevertheless, for reasons which are set out in the ruling and which have relation to the possibility of a new trial if this evidence were admitted the learned Judge refused to admit it. (The prisoner was convicted on both counts.)

Reviews

THE MEDICAL ANNUAL: A YEAR BOOK OF TREATMENT AND PRACTITIONER'S INDEX.—Edited by Sir Henry Tidy, K.B.E., M.A., M.D. (Oxon.), F.R.C.P., and A. Rendle Short, M.D., B.S., F.R.C.S. Sixty-fourth year, 1946. John Wright and Sons, Limited, Bristol. Pp. lxxxii plus 426 with 10 pages of index. Price, 25s.

MANY advances as result of the recent war have found their place in this volume. Two articles outline the advances in medicine and surgery which are applicable in civilian practice. The review on penicillin will be welcomed by many; in addition its uses in various conditions are separately described. Many practitioners in this country will be especially interested in the articles on DDT, researches leading to the discovery of suppressive treatment of malaria by mepacrine and the developments of the treatment of dysenteric disorders. Paludrine is too late to be included in this Annual. There is an interesting study of 100 cases of diabetes which have been watched for ten years with a view to

HAEMORRHOIDS

The immediate relief of irritation

Anusol Haemorrhoidal Ointment can be confidently applied in cases where local inflammation of the anal regions is present. This preparation, because of its soothing, emollient and hæmostatic effect, also relieves the pain

and discomfort caused by hæmorrhoids. Anusol Ointment does not contain narcotics, analgesic or local anaesthetic drugs, and therefore does not mask the symptoms, and improvement is genuine.

Asthenia

The incidence of asthenia and malnutrition demands a preparation of proved tonic powers which is admirably provided in Waterbury's Compound. The intake of this preparation, which contains as its components products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extract and hypophosphites, results in the stimulation of physical vigour and disappearance of the signs of inanition. Waterbury's Compound is agreeable to the palate and is suitable for administration to patients of all ages.

Trustworthy Pituitary Extract

Pitibulin is a thoroughly trustworthy Pituitary (Posterior Lobe) Extract and is characterised by its high degree of stability and unvarying activity.

These qualities are the result of many years' experience in the manufacture of Pituitary (Posterior Lobe) Extract in the laboratories of Allen & Hanburys Ltd.

Pitibulin can be relied upon for use in emergency when prompt action and full activity are essential.

PITIBULIN

Pitibulin is supplied in ampoules of 5 units in 0.5 c.c. or of 10 units in 1.0 c.c., in boxes of 6 or 12 ampoules.
For Asthma: Pitibulin, 2½ or 5 units, with adrenalin, gr. 1/200, in boxes of 6 or 12 ampoules.

ALLEN & HANBURYS LTD. • OLIVE BUILDINGS, CALCUTTA

VITAPHOR

indicated in all cases of VITAMIN DEFICIENCY

VITAPHOR—the perfect TONIC is standardised to contain the following active Vitamins in each fluid ounce :

B₁ 450 International Units
C 1300 International Units
D₂ 1650 International Units

Without these essential vitamins normal health cannot be maintained. Vitaphor also contains the Glycerophosphate of Sodium, Potassium, Strychnine and Magnesium all combined in a suitable base which gives to this Tonic a pleasant and agreeable taste. Prescribe Vitaphor in all cases of Convalescence from acute illness in cases of undevelopment, faulty Nutrition and all "run down" conditions when the body is in a low state of health.

find out what effect the high-carbohydrate low-fat diet had on the incidence of hypertension, cardiac disturbances and ocular changes. This article includes a discussion on the use of insulin and glucose in the treatment of diabetic coma.

The clinical picture and treatment of starvation should interest many physicians in these days. It is surprising to know that the word 'starvation' did not exist before the year 1775, when it was invented and first used by Henry Dundas. Its use was widely scoffed at and he became known as 'Starvation Dundas'. The book covers developments in almost all branches of medicine, and omissions, if any, must be few indeed. It is particularly valuable to those who have neither time nor opportunity to study original papers as they appear in the medical press.

R. N. C.

SURGERY OF THE HAND.—By R. M. Handfield-Jones, M.C., M.S., F.R.C.S. Second Edition. 1946. E. and S. Livingstone Ltd., Edinburgh. Illustrated. Price, 20s.; postage, 7d. (home)

The first edition of this book had such success that it is a surprise to see that six years have elapsed before the second edition has appeared.

Written simply and practically it is an ideal book for the student, the house surgeon and the industrial practitioner. The general surgeon, too, can read the book with profit for it represents experience in the busy out-patient department of St. Mary's Hospital, London.

Emphasis is laid upon rehabilitation in treatment, and rightly. The great advance of surgery in the last decade is the realization that an operation, technically perfect as it must be, is a futility unless kept in proper perspective between the foreground of adequate investigation, diagnosis and preparation, and the background of complete rehabilitation employing every means available. The short-sighted figures of immediate operative mortalities and five-year survivals are disappearing from their position of false priority. Their places are being taken by figures of degrees of recovery of function attainable and maintainable; a far more serious criterion of the value of any surgical procedure.

Mr. Handfield-Jones' book teaches this newer outlook. It is an achievement in its simplicity. Would we had more such forthright statements of individual practice.

Livingstone's productions require no praise. Mr. MacMillan has set a standard in medical publication which would be difficult to better.

A. T. A.

TEXTBOOK OF GYNÆCOLOGY.—By J. H. Peel, M.A., B.M., B.Ch. (Oxon.), F.R.C.S., F.R.C.O.G. Second Edition. 1946. William Heinemann (Medical Books), Limited, London. Pp. xvi plus 467. Illustrated. Price, 21s.

This book is an excellent summary of the latest things in Gynæcology, meant for the undergraduate and the practitioner. All the chapters are written in a very comprehensive manner avoiding descriptive details but dealing fully with the essentials. This remark is not applicable to the chapter on gynaecological operations. This has been dealt in a sketchy fashion. This defect has been made up by inserting a chapter on pre- and post-operative management.

It is really difficult to single out any chapter for special praise. The section on the physiology of the reproductive system and that on sterility and habitual abortion have been very clearly described. The chapter on endocrine therapy contains information of great value to the general practitioner—the appendix on endocrine products will be greatly appreciated by those who may not have sufficient time to devote to gather details of the preparations they prescribe for their patients. The get-up of the book is very good. It is written in plain style, making it easy for the students in India to follow.

We note, however, that the proof-reading has not been carefully done. Common words, e.g. 'uterine', 'curettage', have been wrongly spelt. On page 126 it is

written 'Vagina is only sterile at birth'. When it is meant 'Vagina is sterile at birth only'. Mention has been made of a membranous urethra in the female on page 3.

We do not subscribe to a few of the views expressed by the author. Curettage has been recommended (page 73) in the presence of uterine infection. Hot intra-uterine douches are advocated in abortions. We have never yet seen a case of pyocephalosalpinx as a sequel of recent tubal gestation, and we dare not advise in this case 'When in doubt curette' (page 332).

We have nothing but praise for this book. It is a very suitable and useful textbook for students.

M. S.

DIAGNOSIS AND MANAGEMENT OF THE THORACIC PATIENT.—By Charles Phillimore Bailey, M.D. 1945. (The American Practitioner Series.) J. B. Lippincott Company, Philadelphia and London. Pp. ix plus 334. Illustrated. Price, 24s.

This is a small monograph on Modern Surgical Practice in the management of the more usual intra-thoracic diseases. Throughout emphasis is laid upon first principles and dogmatism as to detail takes no place in the text. Diagnostic and therapeutic pitfalls are described in such a way that the novice in this speciality can take courage in the information he will gain from reading this text and go forward feeling that he knows what to expect and how at least some of the difficulties may be overcome.

The discussions on the more recent techniques of drainage and resection for pulmonary tuberculosis are welcome since these are measures likely to often help to a much larger group of afflicted persons than do the procedures at present commonly employed.

The safety of properly controlled surgical intervention in bronchiectasis is pointed out. It is unfortunate that pulmonary resection is regarded by the general practitioner and even many specialists as an unsafe operation for the bronchiectatic patient. In effect it is a highly satisfactory procedure in properly selected and prepared cases. Such cases, however, can only be selected by those fore-armed with the knowledge of what cures can resection bring about in these desperately ill people.

Management of lung abscess is adequately dealt with in a very neat chapter.

Carcinoma of the lung and oesophagus is discussed at length from the point of view of operative indications and management before and after operation.

The mediastinum and transthoracic gastrectomy receives attention in its anaesthesia and primary closure in chronic empyema.

A small but very practical book worthy of the attention of all physicians and surgeons interested in thoracic surgery.

A. T. A.

SURGICAL TREATMENT OF THE MOTOR-SKELETAL SYSTEM. Two Vols. Edited by Frederlo W. Bancroft, A.B., M.D., F.A.C.S., and Clay Ray Murray, M.D., F.A.C.S. 1945. Parts One and Two. J. B. Lippincott Company, Philadelphia and London. Pp. xix plus 612 with 29 index pages in part I and xix plus from 613 to 1254, with 29 index pages, in part II. Price, £6 for two volumes

Two volumes totalling 1254 pages are devoted entirely to description and illustration of practical procedures in everyday orthopaedic practice. Practically no space is taken by theoretical discussion, diagnostic difficulty or aetiology unless it is absolutely necessary in the interest of clarity.

Each chapter is complete in itself and seems to fairly represent the personal practice of the author. There are 43 collaborators, amongst whom are the most distinguished surgeons on the American Continent, and the 44 chapters contributed are grouped into 14 sections.

The style is reasonably uniform considering the size of the work and the number of authors.

Whilst each chapter is full in details of practice, the feeling left with the reader is always a longing

for more detailed discussion. In fact a book could easily have been written in place of each chapter and the editors are to be congratulated on their management of so large a team and so much concentrated material.

Detailed review of such a work is of course impossible, but reading at random through the work over a period of a month the reviewer finds some of the chapters are far too brief. For example: the problem of bone tumours is dealt with in a mere 29 pages including illustrations; compound fractures in one page; low back strain in two pages. The former is too important to be dealt with so shortly; the latter two so common that detail of practice must be very full.

The most glaring omission is a section on organization and management of rehabilitation. Doubtless these will be included and certain chapters extended in later editions which this work is destined to run to. There is a need for such a work and greater detail, a less discursive style and more balance between subjects of everyday practice and those of occasional appearance would put this particular book amongst the most useful yet published.

Abstracts from Reports

REPORT ON THE WORKING OF THE PUNJAB MENTAL HOSPITAL, LAHORE, FOR THE YEAR 1945

At the commencement of the year 1945 there were 1,224 patients as against 1,221 in 1944. Two hundred and seventy-eight admissions and 36 re-admissions were made during the course of the year and 208 patients were discharged and 87 died leaving 1,243 patients in the hospital at the end of the year. Among the discharges those cured amounted to 101, those improved were 42, those not improved and discharged otherwise were 45 and 20, respectively. The daily average strength of patients in the hospital was 1,231.78 in the year under report as against 1,232.34 in the year 1944.

Occupational therapy is largely employed and as many patients as possible are engaged for weaving cloth, gardening and other outdoor occupations.

The principal types of insanity amongst the patients treated as follows:—

Type of insanity		
Manic-depressive insanity	..	297
Mania	..	203
Melancholia	..	72
Schizophrenia	..	405
Secondary dementia	..	112
Mental deficiency	..	153
Epilepsy and epileptic insanity	..	116
Paranoia and paranoid states	..	59
Cannabis indica psychosis	..	48

Lieut.-Colonel R. M. Lloyd Still, I.M.S., has recently taken over charge as Medical Superintendent of this hospital. It has been decided to demolish the oldest and most unsatisfactory buildings and replace them by up-to-date structures and large gardens.

Besides, in order to bring this hospital into line with other modern hospitals in India, proposals for the improvement of existing medical and attendant staff of the hospital have since been submitted to Government for their sanction. The question of enhancing the number of attendants and menial staff is also receiving attention.

INDIAN MEDICAL GAZETTE

Fifty Years Ago

PLAGUE IN BOMBAY

(Reprinted from *Indian Med. Gaz.*, Vol. 32, 1897, p. 63)

WE are sorry to note that there is no improvement in the prevalence of plague in Bombay. Far from this being the case, the deaths from this cause are gradually increasing. The effect on the town is disastrous. We read that in one ward alone more than one thousand shops are closed, two hundred houses shut up, and many houses, which usually contain a fair number of inhabitants, are only tenanted by keepers. The description of parts of Bombay remind us of the accounts given by DeFoe of the desolate streets of London during the plague of 1665. Nor is this all. Bombay is now quarantined by every port that has direct communication with her. Her trade is temporarily ruined, and it will be a long time before she recovers her former prosperity.

The authorities of Bombay have unfortunately been slow to recognize the gravity of the situation, and it is only now, after the visit of Surgeon-Major-General Cleghorn, that adequate measures are likely to be taken to arrest the ravages of this disease. We are pleased to see that a large number of medical men have been deputed to Bombay on special duty, and that encampments are being formed for the purpose of separating the healthy from the sick. We hope, however, with this measure, the sick will not be allowed to remain in crowded localities, for, without the provision of good nurses to attend to the patients and to secure segregation, the usefulness of the first measure is likely to be rendered futile.

We reiterate what we have stated over and over again that these measures to be of avail must be carried out on the first signs, not of an epidemic, but on the appearance of the first cases, mild or severe. It is a suicidal policy to allow this disease to acquire a hold on any locality when it is possible by prompt measures to stamp it out at its commencement. Possibly, the measures recommended may be considered to be unduly severe and costly; but when we recollect the terrible consequences of inaction, with its resulting epidemic, there ought to be no hesitation whatever in doing what is necessary. Hitherto, health authorities have been too apt to wait until deaths have occurred from plague, and to rest their diagnosis of the disease on its fatality. Recent researches indicate that, like other epidemic diseases, plague has its mild form as well as its severe, and it is instructive to learn from the paper recently read on plague by Dr. Cantlie before the Epidemiological Society of London, that the Calcutta cases of pestis ambulans, which were received with so much incredulity and almost derision by the Medical Board in Calcutta, were considered on their merits in London, and classed along with the cases of pestis minor that had occurred in Mesopotamia and Astrakhan in the seventies, and which had preceded outbreaks of plague in those districts. In this connection, it is a remarkable fact that in the Far East, as stated by Dr. Cantlie in his paper 'From Singapore, the Straits and along the Coast of China as far as Shanghai, between the years 1891 and 1896, we have accounts of a singular

affection of the inguinal glands which occupied the attention of the Singapore and Hongkong branches of the British Medical Association'. He mentions also another form of glandular idiopathic enlargement which was observed to occur in children in an epidemic form. We reproduce Dr. Cantlie's description of the glandular affection among children in Hongkong. 'In the year 1891, I reported twenty-three cases at the Medical Society of Hongkong, and since that date cases have frequently occurred. The affection consists of an enlargement of one gland, seldom more in the necks of children over the sternomastoid about the middle of its length. The swelling is seen upon the sternomastoid, but it might be found to commence, were it met with early enough, in a gland on its anterior border. The disease appears infectious and is attended by feverishness. There is no throat affection, nor is the seat of the disease in the parotid. We, the medical practitioners, styled the condition for convenience' sake mumps, but we all admitted that neither the parotid nor the submaxillary glands were the seat of trouble. It will be remembered that the term "peculiar form of mumps" was employed by some to designate the Astrakhan disease in 1877'.

In the years 1893-94, and since in Hongkong, cases of fever of a typho-malarial type occasionally presented, in the third or fourth week, a general enlargement of lymphatic glands, which lasted for a week or ten days and then subsided. They were deemed interesting cases at the time, but, with the fresh light thrown upon them by recent investigation, more especially the researches in Calcutta, they assume a new aspect.

Thus, the more the matter is enquired into, the more evident it becomes that only in exceptional circumstances does plague immediately acquire epidemic proportions in a locality, and it appears that epidemics are more usually ushered in by the occurrence of a succession of mild cases of *pestis ambulans* (sometimes called *pestis minor*). And it is important that medical practitioners should be made acquainted with this form of the disease, and with its relationship with the more fatal type of the disease. For, it is obvious that if the connection between these forms of disease is granted, it is the mild forms which are likely to escape detection in the first instance, and, by their spread, lay the seeds of an epidemic which may become uncontrollable.

PLAGUE IN INDIA

(Reprinted from *Indian Med. Gaz.*, Vol. 32, 1897, p. 65)

With reference to the plague in India, *The British Medical Journal* of 26th December, says:—'The real crux of scientific discussion centres round the Calcutta cases. The *pestis minor* or *pestis ambulans*, as it is termed, evidently prevails in that city, and the experts and others are much perplexed thereby. One man finds the bacillus in "plague" cases only to have it denied by others.

'The idiopathic buboes—*bubon d'emblee*—which for years has engaged the attention of medical men in the Far East, from the Straits Settlements and Singapore to Hongkong, seems to have reached the latitude of Calcutta. The Shropshire Regiment, moreover, the very regiment which was lying in Hongkong during the plague epidemic in 1894, and from which some hundreds of men volunteered to do "plague work" in Hongkong, is now in Calcutta. They are showing non-venereal buboes in extraordinary numbers, and their ailment is viewed with suspicion by some, and classed with others as ordinary occurrences of buboes. But we fail to recall any such disease in our textbooks, and can only join in the view that these are cases of mild plague or a separate disease.

'As will be seen from the report in another column. Dr. Cantlie in his paper on the "Spread of Plague" read before the Epidemiological Society on 16th December, 1896, discussed this aspect of the subject. He stated that idiopathic bubo—*bubon d'emblee*—has been prevalent on the China Coast for several years, so

much so that active correspondence went on between the Hongkong and Singapore Branches of the British Medical Association on this very subject as to their nature. The subsequent outbreak of plague in China raised the question whether these idiopathic buboes should be included under the heading *pestis minor* or whether they were a separate and hitherto unrecorded disease.

'The Calcutta observers are evidently divided into two camps: the exponents of the bacillus declare that a bacillus identical in microscopic appearance, but differing in toxic powers, is met with in these cases of idiopathic bubo and in those of the ambulatory form of plague which are at the present moment met with in Calcutta. Their opponents reject the bacillus altogether, denying that it is in any way allied to the true plague bacillus. The issue of the investigation will be awaited with interest.'

Any Questions

DEGREE OF IMMUNITY IN A POOR TAKE OF PRIMARY VACCINATION

SIR,—A child, aged 3 months, was given primary vaccination by two linear scarifications. Only one scarification has taken and that also at one point only of the scarification. There has been no general reaction.

In view of the poor take of the vaccination could you kindly let me know through your esteemed journal and also if possible earlier by post as to (1) how long will this immunity last to a sufficient degree to face even a heavy exposure, and (2) whether it is advisable to re-vaccinate the child without waiting for the next year and if so how soon it should be done.

Yours, etc.,

S. K. BANERJEE, M.B.

192A, LANSDOWNE ROAD,
CALCUTTA.

[The interpretation of the findings is that the child had not yet fully developed tissue response to vaccinia and so reacted poorly. He should be revaccinated this year and again next year if this year's revaccination fails. Two or three months' interval since the first vaccination will be desirable, one should not depend upon this last vaccination at all.—R. B. L.]

UMCKALOABO

SIR,—Please tell me the present status of UMCKALOABO in the treatment of tuberculosis.

1. Do you consider it does have value?
2. Where may I obtain it?
3. In what forms is it prepared, and how administered?
4. Where may I obtain a brief treatise on this drug and its use?

COLFAX,
CALIFORNIA, U.S.A.

I. R. KILGORE, M.D.

[The drug (in powder form) can be obtained from the headquarters of the company at 204-6, Worple Road, Wimbledon, London, S.W.20, England.

The results of treatment by Calcutta specialists have been disappointing.

It is available at Calcutta from Messrs. Frank Ross & Co., Ltd., 15/7, Chowringhee, Calcutta.

Literature: A book under the title of 'Tuberculosis: its treatment and cure with the help of Umckaloabo (Stevens)' was written by an English physician and published by B. Fraser & Co., Cottenham Park, London, S.W.1, some years ago.—A. C. U.]

Service Notes

APPOINTMENTS AND TRANSFERS

MAJOR F. H. A. L. DAVIDSON made over charge of the office of the Medical Officer of the *Dacca Central Jail* to Major W. J. Virgin in the afternoon of the 21st December, 1946.

The Secretary of State for India has sanctioned the reversion to military employment, of the under-mentioned Indian Medical Service (Civil) officers with effect from the 18th November, 1946.

Madras

Major P. L. O'Neill,
Major D. Tennant.

LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

To be Lieutenant

F. G. Orton. Dated 22nd February, 1946.

PROMOTIONS

Colonel to be Major-General

A. H. Harty, C.I.E., K.H.P. Dated 12th November, 1946.

Lieutenant-Colonel to be Colonel

L. K. Ledger, O.B.E. Dated 12th November, 1946.

LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Lieutenant to be Captain

Frederick George Orton. Dated 22nd February, 1946.

RELINQUISHMENTS

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Lieutenant-Colonel :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Ty. Lieutenant-Colonel T. L. W. McCullagh. Dated 1st November, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

Ty. Major Amar Parsad Ray. Dated 10th October, 1946.

Major Rajinder Singh Dhillon. Dated 12th November, 1946.

Ty. Major P. V. Balakrishna Marar. Dated 16th November, 1946.

Ty. Major B. Sundararamamurti. Dated 21st November, 1946.

Ty. Major N. V. Nene. Dated 29th November, 1946.

Ty. Major Babu Ram Mahajan. Dated 14th December, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

Captain Valanagam Srinivas Raghavachari. Dated 8th October, 1946.

Captain D. K. Guha. Dated 9th October, 1946.

Captain Andrew Peters. Dated 14th October, 1946.

Captain J. Vaidhianadhan. Dated 29th October, 1946.
Captain Pottivale Vadivale. Dated 29th October, 1946.

Captain V. C. Kamaraju. Dated 4th November, 1946.

Captain K. I. George. Dated 12th November, 1946.

Captain Gopal Narayan Datar. Dated 14th November, 1946.

Captain Radha Raman Lal, M.C. Dated 16th November, 1946.

Captain Devki Nandan Mehta. Dated 18th November, 1946.

Captain K. N. Raman. Dated 21st November, 1946.

Captain P. Damodaran. Dated 23rd November, 1946.

Captain K. C. Banerjee. Dated 23rd November, 1946.

Captain V. K. Pillay. Dated 27th November, 1946.

Captain H. S. Malik. Dated 1st December, 1946.

Captain B. Ramchandran. Dated 2nd December, 1946.

Captain V. R. Sane. Dated 6th December, 1946.

(WITHIN INDIAN LIMITS)

Captain H. S. Henry. Dated 27th October, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of C. P. and Berar with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Captain C. N. Pradhan. Dated 7th June, 1946.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

A. K. MUKERJI, M.B.

Helminthology Research Department

(From the School of Tropical Medicine, Calcutta)

THE value of tetrachlorethylene in the treatment of hookworm disease is well established, and it has rightly come to occupy a very prominent place in the armamentarium of the practitioner in the tropics. The popularity of this drug is due to its ease of administration, relatively low cost, low toxicity and high efficacy in eradicating the worms. A single treatment would remove more than half of all hookworms and two (occasionally three) treatments eradicate the infection altogether or bring it down to a negligible level. The drug has a pleasant smell and usually produces no untoward effect except some drowsiness. Toxic symptoms have been noted only rarely, and in spite of its widespread use, not a single case of fatal poisoning from it has been recorded. The following case is probably the first death caused by tetrachlorethylene and seems worth recording.

Case Report

A street beggar, aged 30 years, was admitted to the Carmichael Hospital for Tropical Diseases under one of us (R. N. C.) on the 25th April, 1946. His chief complaints were pain and burning sensation in the epigastrium with occasional vomiting and chronic diarrhoea—duration one year. He also had swelling of the legs for about two months.

Examination.—The patient was emaciated, weighing only 70½ pounds, and had marked oedema of the legs and feet. The heart and lungs were normal. There was slight rigidity in the right hypochondrium, the spleen and liver were not enlarged. Blood pressure was 110/55 mm. Hg.

Laboratory reports.—Blood: hæmoglobin 7.15 gm. per cent, red cells 4.15 millions, cell volume 29 per cent, mean corpuscular volume 69.8 c.µ., mean corpuscular hæmoglobin 17.2γγ, mean corpuscular hæmoglobin concentration 24.6 per cent, white cells 8,000 per c.mm. with neutrophils 66 per cent, lymphocytes 31 per cent, monocytes 1 per cent and eosinophils 2 per cent. Total protein in blood (copper sulphate method)—6.1 grammes per cent (albumin 2.0 and globulin 4.1). Van den Bergh reaction—negative. Wassermann reaction—negative.

Stool: no protozoa, hookworm ova 1,100 per c.c. Urine: no abnormality.

Course and treatment.—For the diarrhoea (3 to 4 loose watery motions a day) he was given sulphaguanidine, 2 grammes every four hours for seven days, along with multivitamin tablets, 2 tablets twice a day. The diarrhoea stopped, and from 4th May he was put on iron (hæmosan, 2 tablets three times a day) and magnesium trisilicate thrice daily after meals. On 9th May at 7-30 a.m. he was given 3 c.c. of tetrachlorethylene shaken in an ounce of sodium sulphate mixture (containing 4 drachms of sodium sulphate). At 10 a.m. he was found to be drowsy (a not uncommon hypnotic effect of the drug) but responded to questions. He complained of pain in the abdomen and had one big vomit of greenish colour. At about 1 p.m. the pain increased in severity, and he was rather restless, but the abdomen was soft and the pulse was fairly good. He was given atropine gr. 1/100 and somnifen 2 c.c. hypodermically as well as 50 c.c. of 25 per cent glucose solution intravenously. There was no improvement, and in the evening the pulse became feeble. Normal saline with 5 per cent glucose was given by the intravenous drip along with coramine injections every four hours. The condition however deteriorated at night, and he died the next morning.

Post-mortem report.—‘Body thin and emaciated, oedema on both feet. Rigor mortis present.

Pleural cavity—no effusion.

Lungs—right 240 gm., normal; left 220 gm., normal.

Pericardial sac—normal amount of clear fluid.

Heart small, 200 gm., epicardium normal.

Right auricle slightly distended. Left ventricle firm and contracted, chamber almost empty. Myocardium appears atrophied. Mitral valve shows old lesion; bases of cusps fibrotic. Aortic and pulmonary valves appear normal.

Abdominal cavity—small quantity of hæmorrhagic fluid present. Parietal peritoneum appears normal. Omentum shows venous congestion specially of the free margin.

Stomach—empty except for a small amount of mucoid fluid, mucosa shows scattered punctiform hæmorrhages; pylorus feels hard, no evidence of peptic ulcers.

Duodenum pale, solitary follicles enlarged.

Jejunum—in the upper third, mucosa appears pale; deep congestion of the mucosa begins at the middle third as a well-defined inflammatory process and extends throughout the rest of the jejunum and the whole length of the ileum. Lower part of the ileum looks almost blackish owing to intense congestion—an isolated patch of deep ecchymosis is present about one inch above the ileo-cæcal valve.

Cæcum—shows perityphlitis, mucosa oedematous, no evidence of ulceration.

Appendix normal. Colon—nothing abnormal seen.

Liver—small, 850 gm., pale and soft, pattern indistinct.

Gall-bladder—adhesions with omentum, small intestine and duodenum—contents appearing purulent, a condition of septic cholecystitis.

Spleen—small, 50 gm., soft and shrunken.

Pancreas—normal.

Kidneys—right 90 gm., left 50 gm., both kidneys smaller than normal. Demarcation between cortex and medulla very indistinct, capsule strips easily.

Bladder—empty, normal.

Diagnosis—acute hæmorrhagic enteritis.

Discussion

Compounds of carbon and halogens have been in use as anthelmintics against hookworm for the last 25 years, their efficacy depending on the chlorine content. The first one that was tried was carbon tetrachloride, but owing to its toxic action on the liver and kidneys and incidence of some fatalities it has largely been replaced by tetrachlorethylene. The latter is very insoluble in water, non-irritating and does not produce any local effect on the mucous membrane. According to Lamson, Robbins and Ward (1929) tetrachlorethylene differs from carbon tetrachloride in not being absorbed, from the intestinal tract of dogs in the absence of fat. If fat is present or if enormous doses are given to animals of different species, absorption may take place with symptoms and even death, but these symptoms are those of an overdose of a hypnotic not those of chemical changes secondary to liver damage, as in the case of carbon tetrachloride. There has been no report of deaths with this drug and this is correlated with its low rate of absorption in the absence of alcohol or fatty substances. Clinical observations, however, point to the fact that the drug is absorbed to some extent from human intestine but not in amounts sufficient to produce damage of the kidney or liver cells (Chopra, 1936). In a few cases marked symptoms of intoxication have been noted even after therapeutic doses. Kendrick (1929) reported one case in which after taking 3 c.c. of the drug the patient became unconscious with barely perceptible pulse; he was revived after two injections of strychnine and digitalin. Wright, Bozicevitch and Gordon (1937) mentioned the case of a boy of 11 years who after 1.1 c.c. of the drug became dizzy and cyanosed and lost consciousness but recovered after an injection of adrenaline solution. The child was subsequently found to have pulmonary tuberculosis. Hare and Dutta (1939) reported a girl of 18 who after taking tetrachlorethylene had severe vomiting followed by drowsiness which was relieved by application of cold to the head. And more recently Sandground (1941) described two cases of coma after administration of the drug with disappearance of most of the peripheral reflexes. Both recovered after injections of metrazol. In all these instances the

effects were temporary and of a narcotic nature, but there is no case on record, so far as we know, in which tetrachlorethylene had caused a severe local action on the intestine as in the case we have described.

At the time of admission the patient was obviously in a state of chronic malnutrition of which the main clinical features were emaciation and cedema of the legs. He was a street beggar, and though 30 years old, weighed only 70½ pounds. He had suffered from a chronic abdominal pain, and this was probably due to cholecystitis which was revealed only at the autopsy. The patient had also chronic diarrhoea which responded well to sulphaguanidine, but there was no old gross pathological lesion in the intestine suggestive of a specific infective cause for the diarrhoea. It is possible that it was a 'nutritional diarrhoea'. Unfortunately the nature of changes in the intestine is not definitely known as no histological reports are as yet available. The heart, liver and spleen were all small in size. It may not be unreasonable to assume that the small intestine was involved in the process of malnutrition and was particularly vulnerable to the effects of tetrachlorethylene. Although it is not possible to arrive at a definite conclusion on the point from a single case we feel that it would be wise to withhold anthelmintics in hookworm cases with obvious evidence of malnutrition. This is comparable to the treatment of hookworm disease with severe anæmia in which no anthelmintic treatment is given until the hæmoglobin level is brought up to a safe level by iron therapy.

Our thanks are due to Major K. Banerjee for the post-mortem report.

STAB WOUNDS OF THE ABDOMEN

A REPORT ON 25 CASES

By ASITA LAL SOM, M.B., F.R.C.S.

Teacher of Clinical Surgery, Campbell Hospital, Calcutta
and

MURARI MOHAN MUKHERJEE, M.B.

Resident Surgeon, Campbell Hospital, Calcutta

THE experiences of last two great wars have taught us the principles of treatment of abdominal wounds caused by bullets or splinters. We have had some experience of the stab

wounds of the abdomen during the Calcutta disturbances and we feel that our observations should be recorded, although owing to the extreme emergency and the heavy inrush of casualties there was little time or opportunity to make very accurate observations and to prepare accurate statistics.

An ambulance driver, the patrolling police or military personnel usually picked up the casualty from the street and took him to the nearest hospital. First aid, which ought to have been given, was seldom given and the casualties were brought as they were found in the street. In a few cases the prolapsed viscera were accidentally discovered under the clothing while attending to the other wounds. The majority of the casualties reached the hospital within six hours. Only one case was brought after forty-eight hours.

The out-patients department of the hospital received the casualties first. The officer on duty there made a quick survey of the patient, gave a dose of morphia if he was very restless, checked the temporary dressing where applied, covered him up with a blanket and sent him immediately to the in-patients department.

We made a thorough examination of the general and local condition. It was noticed that shock was not so marked and constant a feature in uncomplicated abdominal cases (unlike what obtains in gunshot wounds of the abdomen). By uncomplicated abdominal cases we mean pure abdominal stabs in contradistinction to double or multiple injuries, i.e. abdomen and head injury, abdomen and sucking chest wound, etc. The degree of shock depended mostly on the amount of hæmorrhage from the visceral injury. Shock was estimated from the blood pressure and pulse rate, other recent methods not being available. We classified shock into three groups—mild, moderate and severe (*vide* M.R.C. War Memorandum no. 1 on traumatic shock).

Pulse rate		B.P.
Mild ..	90-120 p.m.	Syst. above 95 mm. of mercury.
Moderate ..	120-140 p.m.	Syst. 70-90 mm. of Hg.
Severe ..	140-160 p.m.	Syst. below 60 mm. of Hg.

TABLE I
Shock

	Stab wounds	Gunshot wounds for comparison
No shock	5	...
1. Mild shock ..	12	...
2. Moderate shock ..	7	6
3. Severe shock ..	1	4
	<u>25</u>	<u>10</u>

Resuscitation was started immediately in the suitable cases. Dried human plasma or serum was used. One or two pints was usually transfused. These were found very useful and handy owing to superior keeping quantities and quick availability. In some cases we used isotonic saline with or without 5 per cent glucose for resuscitating purpose. Morphia was not given until a tentative diagnosis of intra-abdominal injury was made. If after the usual treatment of shock the patient's condition deteriorated, visceral injury was strongly suspected. In our series there was not a single case of 'negative belly'.

According to the sites of the wounds, we classified our cases into five groups:—

TABLE II

Sites	Number of cases	Number of cases with prolapsed viscera
Thoraco-abdominal ..	6	0
Upper abdominal (above umbilicus) ..	7	4
Flanks ..	8	4
Back of loin ..	2	0
Buttock (ischio-rectal region) ..	2	0
	<u>25</u>	<u>8</u>

Upper abdominal and thoraco-abdominal wounds were more towards the sides of the body resulting from the position of the assailant at the back or side of the victim. The two buttock cases were stated to be standing on the bumper of a bus when stabbed.

The following signs and symptoms were the guiding factors for exploration in our cases:—

1. Prolapse of the viscera.
2. The site and severity of the wound.
3. Pulse rate near about 110 per minute.
4. Pain and tenderness—a very constant feature.
5. Rigidity—a very constant feature in abdominal cases (also noticed in some of the lower chest wound cases).
6. Vomiting was of less significance. It was noticed in stomach cases only.
7. Hæmorrhage, though surmised, could not be correctly diagnosed unless it was profuse, causing shifting dullness and signs of internal hæmorrhage, but one should not wait for its confirmation.
8. Obliteration of liver dullness was rare in our series of cases. It may be confirmatory but one should not wait for it.

Aseptic dressings were applied in the operation theatre after the anæsthesia.

Anæsthesia.—Gas, oxygen and ether were anæsthesia of choice, if possible through an endotracheal tube.

Operation.—The idea was quick in and quick out but at the same time rapid inspection of other viscera was not neglected.

Incisions were made according to the sites of the injuries.

(i) For the upper abdominal wounds paramedian incisions were used.

(ii) For stab wounds in loins or costal margin transverse incisions were used.

The stab wounds were excised scrupulously down to the peritoneum and sutured in some cases, but in other cases so much care was not taken and only the skin was excised. The results of the latter were also encouraging. The prolapsed omentum was always excised. Prolapsed small intestine was usually replaced after thoroughly cleaning with saline and suturing any perforation or injury. In the case of large intestines it was exteriorized in some cases and in others it was replaced with repair of its perforation and a drainage tube was put through the flank with or without caecostomy. At times we had to enlarge the stab wound in order to replace the prolapsed viscera. The usual practice of sprinkling of sulphathiazole was not neglected in any case.

As soon as the peritoneal cavity was opened, we looked for gas, blood and gastro-intestinal spillage but we were surprised to find that gas was conspicuous by its absence, contrary to what is found in cases of perforation of any hollow viscus. Gastro-intestinal spillage was markedly less or absent though more than one perforation was seen in many cases. Blood was present in most of the cases. When the amount was profuse and when there was no extravasation of gastro-intestinal contents, autotransfusions were done with very encouraging results. The size of perforation was usually small and no eversion of edges (cf. G.S.W.) and in fact at times we had to squeeze the viscus to discover the site of the perforation.

Stomach.—Perforations of the stomach were seen mostly in thoraco-abdominal stab wounds and were, usually, associated with injury to the liver and the pleural cavity. Most of the cases were received in the morning before the principal meal. There was no soiling of the peritoneal cavity with stomach contents. Bleeding was not appreciable as the perforations were away from the big vessels. The fundus and the pylorus were the usual sites. In one of the fundal cases the site of perforation was reached without difficulty through the left upper paramedian incision as distension was absent. The results of these cases were satisfactory—75 per cent of cases survived.

Liver.—Liver was injured in almost all the thoraco-abdominal and upper loin cases but the bleeding was not profuse. It was an incised wound with clean-cut margins and not lacerated as in most gunshot wounds. Suturing was attempted with success in some cases. Bleeding stopped in some cases before intervention. No real plugging was possible due to lack of space,

so usually a rolled gauze was left against the bleeding surface. A corrugated rubber sheet was placed between the gauze and the neighbouring viscera. No case developed biliary peritonitis or fistula. The results were good as 80 per cent survived.

Spleen.—Spleen was injured by the stab wound situated near the left costal arch. The injuries were sharp cuts and without lacerations similar to those of the liver. Haemorrhage was not profuse. The simple method of putting in a roller gauze between the diaphragm and the cut margins of the spleen proved successful. The plug was brought out through the flank. Ballance's sign and referred pain were absent, probably due to little haemorrhage. Splenectomy was done in half the cases with depressing results. Two of our four cases were treated by conservative method and were saved. Results should be good if the conservative method is followed.

Small intestine.—Perforations were usually single and small unlike G.S.W. The question of resection never arose. No extravasation of intestinal contents was noticed. Severe bleeding was associated with injuries to the mesentery. The mesenteric rent was never big enough to jeopardize the vascular supply of the corresponding segment of the intestine. In a few of the prolapsed cases the intestines were found to have escaped an injury. Result was good as 90 per cent survived.

Large intestine.—Injury of the colon was associated mostly with stab wounds in the flank. When the perforation was small, colon was sutured and reposed. The paracolic gutter or retroperitoneal space was drained and the site of injury was disturbed as little as possible to avoid contamination of the general peritoneal cavity. When the injury involved a major portion of the circumference of the gut either the injured colon was exteriorized or closed with a caecostomy. There were injuries of the superficial layers of the colon, i.e. wall, with lot of haemorrhage. Haemorrhage was severe in the colonic injuries and faecal contamination was present in most of the cases except where the opening was very small.

Rectum.—Two cases of stab through the buttock came without any involvement of the rectum and hence proximal colostomy was not done.

Bladder.—Not a single case of stab through hypogastrium or injury of bladder was found.

Gall-bladder.—One case was associated with injury of the liver and duodenum. The G.B. was repaired and the Rutherford Morison's pouch was drained. There was profuse biliary extravasation. Cholecystectomy was the operation of choice, but in this case it was considered unjustifiable owing to patient's grave general condition. Definite conclusion is not possible from our series.

Duodenum.—Two cases were met with, one as described above and the other was a stab

through the upper epigastrium dividing the first part of the duodenum in more than half its circumference. As the patient's condition was bad gastrojejunostomy was not done.

Kidney.—There were two cases in our series, one was a recent one and the other came late with a urinary fistula through the stab wound. The stabs were through the back below the ribs. The recent case was plugged through the back as the patient passed no blood with urine to start with. He developed profuse hæmaturia on the 5th day. Conservative treatment with whole blood transfusion was of no avail and ultimately we performed nephrectomy with unfortunate result. These cases are usually associated with perirenal hæmatoma and the renal pedicle becomes friable, so the ligation should be done in section. In peripheral or cortical injuries suturing or gauze plugging should be attempted. Associated intraperitoneal injuries were not seen.

Abdominal injuries complicated with head or chest injury should be judged on their merits. Minimum interference should be the watchword to prevent additional shock.

Example.—A boy of 12 had stab wound in right flank with prolapse of the colon. He had 9 injuries on the head with fracture of the skull. Nothing but resuscitation was done. On the third day the prolapsed viscera was partly gangrenous and there was distension of the abdomen. The loop of bowel about five inches long was excised and the two ends drained. Two self-retaining catheters were fixed with the proximal and distal colostomy openings. Peptonized milk was given through the distal colostomy opening for a few days. The head injuries were dealt with two days later. The boy is living and an ileotransverse colostomy has recently been done. He is progressing well. This boy had no perceptible pulse at the wrist for nearly 24 hours and no one thought he would survive.

TABLE III
Mortality

	Number treated	Number dead	Per cent
Stab cases ..	25	4	16
Gunshot cases ..	7	4	57

(Out of 10 G.S.W. cases 3 cases died before operation.)

Discussion.—It will be evident from table I that out of twenty-five cases, one patient only had severe shock and the majority of the cases belonged to group I, i.e. mild degree of shock. Why was it so? Probably it was due to quick transport, absence of laceration of tissues, small amount of hæmorrhage, absence of or insignificant gastro-intestinal spillage. The patient with severe shock had rupture of the gall-bladder, duodenum and liver. There was fair amount of blood and bile in the peritoneal cavity resulting in severe shock. Abdomino-thoracic cases

had also moderate degree of shock probably due to associated injury of the pleural cavity and diaphragm. Shock was mild and sometimes negligible in prolapsed viscera cases.

From table II, we notice that there was prolapse of viscera in 33 per cent of cases. Prolapse of viscera was due to gaping of the abdominal wall, especially when the muscles were cut across the direction of their fibres helped by the spasm of the rest of the abdominal wall.

All the patients with prolapsed viscera survived. Not a single case developed intraperitoneal infection although in one case a loop of the small bowel was found lying under dirty clothes for hours. Luckily that loop of the bowel escaped penetrating injury. The loop of the bowel was replaced after thorough toileting and sulphonamide dusting.

Hæmorrhage was free and moderately severe in hollow viscera and mesenteric injuries in contradistinction to solid viscera injury. Moreover the bleeding was marked in large bowel injury. This was probably due to retraction of the muscular wall of the intestine, but the blood vessels supplying the wall could not contract at the same time due to their oblique course. On exploration it was found that there was no appreciable active bleeding from the cut surface of the solid viscera, as the blood was coagulated by that time, the thin clot acting as a sort of plug thus preventing further oozing. Though suturing of liver was done in some of our cases, we are of opinion that most of the liver wounds can be treated conservatively by muscle or omental plug or packing. Sutures often do not hold and may cause further bleeding.

In splenic injuries, if the organ is not badly injured or its vessels have escaped injury and if it be found not bleeding when the viscera are explored, one should not do splenectomy. It will be noticed that out of the four cases of splenic injuries of our series two cases, where we did splenectomy, proved fatal, whereas the other two being treated conservatively recovered. The same remark applies for kidney injuries as well.

If the injury is not severe and bleeding is found on exploration to have stopped, and the hilum and the ureter have escaped, one should not do nephrectomy. If nephrectomy is decided the pedicle should be divided in sections instead of mass ligature. It should be realized that when the renal pedicle is surrounded by infected clot, the pedicle becomes friable and the mass ligature is liable to cut out. In our case we did nephrectomy as we thought the hæmorrhage (hæmaturia) to be secondary in nature and the wound was through and through in the central part of the kidney bordering the hilum. Had we pursued a conservative attitude, i.e. suture, pack, and drain, the case might have been saved.

Conservative treatment with secondary splenectomy for minor injuries of the spleen is advocated nowadays.

Gastro-intestinal spillage was surprisingly absent in the stomach and in most of the small intestine cases. If there was any extravasation—it was very insignificant. Most of the abdominal patients were received in the morning before the principal meal. Absence of or insignificant extravasation was probably due to comparative emptiness of the gastro-intestinal tract helped by temporary inhibition of the peristalsis subsequent to injury. The gastro-intestinal injuries were small in most cases and margins were clean cut and partly inverted (*cf.* G.S.W.). The small rent and the plastic adhesion of the incised surfaces with blood and serum were also probably contributory factors. We have observed that wounds of the large intestine leak universally in contradistinction to the wounds of the small intestine. This is probably due to the comparative fullness of the large bowel and the severance of the short longitudinal muscular coat (*tinix*).

We did six auto-transfusions with no evidence of blood infection in any case. We did not take any risk in transfusing blood from the peritoneal cavities in penetrating wounds of the bowels even though there was no apparent extravasation of the bowel content. Blood was only taken from mesenteric injury cases.

In view of the fact that sulphonamide and penicillin appear to be equally effective in the prevention and treatment of peritonitis, we used sulpha drugs intraperitoneally in all cases due to easy availability and lack of technical difficulties. We also used parenteral penicillin in some cases in addition to oral sulpha drugs.

From table III it will be evident that amongst twenty-five cases of stab wound of abdomen only four died (16 per cent mortality), out of seven cases of gunshot wound of abdomen four patients died (57 per cent mortality). This severe mortality in gunshot wound cases and the four deaths in stab cases were due to shock and hæmorrhage.

Summary

1. Shock in stab wounds was not usually marked.

2. The common sites were upper abdomen or flanks.

3. Prolapse of the viscera was fairly common and the result of treatment was very encouraging.

4. Transverse incisions afforded excellent approach to the ascending and descending colon. It also at the same time prevented unnecessary exploration of the general peritoneal cavity and spread of infection. It also helped in putting a retroperitoneal drain and in establishing an artificial anus whenever required.

5. Hæmorrhage was marked in the hollow viscera and mesenteric injuries in contradistinction to the solid viscera injuries. When the abdominal bleeding was profuse and there was no perforation of bowel auto-transfusion was done with success (3.8 per cent sodium citrate

solution was used). 10 per cent 10 c.c. ampoule of sodium citrate is available in the market (B. I. Company). One ampoule is required for every 100 c.c. of blood.

6. Most of the solid viscera injuries could be treated conservatively, *e.g.* pack, suture and drain. Nephrectomy and splenectomy should be done with great caution.

7. Gastro-intestinal spillage was absent in some cases and in others it was conspicuously insignificant. Extravasation was always present in the large bowel injuries.

8. Peritoneal infection was markedly absent—except one case of retroperitoneal hæmatoma threatened to form an abscess but it subsided with sulpha and penicillin drugs.

9. Multiple injuries were treated conservatively, depending on the merits of the case.

We convey our grateful thanks to Major E. H. Lossings, M.D., I.M.S., Superintendent of the Campbell Hospital, for allowing us to utilize the hospital records.

A NOTE ON ESTIMATING HÆMOGLOBIN

WITH ONE CUBIC MILLIMETRE OF BLOOD

By M. N. RAO
and
G. KARMAKAR

(Section of Biochemistry, Nutrition and Physiological Hygiene, All-India Institute of Hygiene and Public Health, Calcutta)

THE common laboratory method for estimating hæmoglobin is the Hellige method of converting hæmoglobin into acid hæmatin and computing the colour against a standard. The method requires 20 cubic millimetres of blood. Working with monkeys on experimental anæmias, this amount can easily be drawn either by puncturing the ear or the posterior tibial vein. But if the experimental animal happens to be the rat, it would be difficult to collect 20 cubic millimetres of blood, unless the blood is collected from the heart direct. The usual method followed is to snip the tip of the rat's tail with scissors and collect a few cubic millimetres of blood. A number of cuttings are required to collect blood enough for one estimation by Hellige method. The short length of the tail thus permits only a few hæmoglobin estimations on the animal. So it was thought that if each

estimation of hæmoglobin as well as corpuscle-counting could be done with the blood collected by scissoring the tail once a number of estimations is possible during the course of the experiment. Moreover, the monkey as an experimental animal for work on anæmias is not the best suitable animal in that the duration of the experiment is prolonged, whereas the rat would be more suitable in that the duration of the experiment is less, provided the difficulties of doing repeated estimations are overcome. The following method seems to obviate the difficulties. In fact, the hæmocytometer fluid left over after ordinary clinical use can be utilized for hæmoglobin estimation by the method described below :

Principle

The pseudoperoxidase reaction of the blood is made use of as this method is the most sensitive known for detecting very minute quantities of blood. The method adopted is based on Wu's (1923) as modified by Bing and Baker (1931).

RBC counting

The tip of the rat's tail is scissored and as much blood as could be collected is drawn into the pipette. The hæmocytometer manufactured by any reputed firm has one cubic millimetre markings but even otherwise the instrument can be calibrated by weighing pipetted mercury. One cubic millimetre of blood is the minimum amount that has to be drawn, and the blood diluted with normal saline to the dilution mark. The counting is done as soon as possible, preferably within half an hour to obviate marked changes or lysis of the corpuscles. The remaining fluid which is well over 0.5 c.c. is used for hæmoglobin estimation. The dilution factor of the blood in the pipette also is noted.

Hæmoglobin estimation

I. The standard benzidine solution.—Stock solution of purified benzidine is made as described by Sankaran and Rajagopal (1938). One additional point may be mentioned in the method. The commercial benzidine though marked pure give always a coloured solution and requires purification. During the course of purification the benzidine solution in warm alcohol is extracted by charcoal. It requires nearly ten to fifteen extractions before the solution is clear. But usually there is always a residual colour of the solution resistant even to this treatment. This can be prevented by the use of gradually less warm alcohol in the last few extractions. The criterion of the purification of benzidine is by a blank test. A 1 per cent solution of dried purified benzidine is made by first dissolving in 20 c.c. warm glacial acetic acid and 30 c.c. of distilled water and 50 c.c. of 95 per cent alcohol. Two c.c. of this reagent with 1 c.c. of distilled water and 1 c.c. of 1 to 2 per cent hydrogen peroxide should not give a colour in 2 hours. If this mixture is diluted to 20 c.c.

with 20 per cent acetic acid and viewed through a thickness of about 1 c.cm. it should be practically indistinguishable from distilled water. Even if there is a slight coloration, the use of Pulfrich photometer gives the correction value, as it has been found that by reckoning the extinction co-efficient of this value while calculating the extinction co-efficient after the blood is added the error can be eliminated.

II. The standard blood solution may be prepared from blood whose value is calculated from any of the standard methods. The usual diluent of the standard blood is 1 per cent boric acid. Instead normal saline can be used just as in the case of the unknown and the estimation done forthwith. If the standard blood solution is to be preserved for some days, no difference in results is noticed when 1 per cent boric acid is used.

III. The method.—The fluid remaining over in the hæmocytometer after the counting of rbc is used for hæmoglobin estimation. To each of the three test-tubes is added 1 c.c. of benzidine solution. 0.5 c.c. of the blood solution of known hæmoglobin content is added to the first test-tube, that of the unknown hæmoglobin to the second test-tube and distilled water to the third. 0.5 c.c. of 1 to 2 per cent hydrogen peroxide is added to all of them when the colour deepens from green to purple in two hours. Then suitable but equal amounts of 20 per cent acetic acid is added to each of the test-tubes and the colours are matched in Pulfrich photometer. The acetic acid is used as a diluent either to make up the cell volume or to reduce the colour intensity. The cells used are 0.5 c.cm. thick and the filter is the green filter no. 11. One cell is always filled with the control solution where no blood has been used and the other cell is filled with the solutions of blood of known and unknown hæmoglobin content successively. The density drum corresponding to the cell filled with the blood solution is set always at zero and the other drum containing the control solution is rotated in order to find the extinction co-efficient. The results are calculated thus :—

$$H_u = \frac{E_u}{E_s} \times H_s$$

Where H_u = hæmoglobin content of the unknown

H_s = hæmoglobin content of the known

E_u = extinction co-efficient of the unknown

E_s = extinction co-efficient of the known

Once H_s and E_s are determined the factor $\frac{H_s}{E_s}$ becomes constant for the same particular sample of reagents and therefore the formula becomes—

$$H_u = \frac{H_s}{E_s} E_u$$

= $K.E_u$ where K = constant.

A sample of blood of known hæmoglobin content was examined and the value of the constant 'K' was calculated out to be 56.0. So in order to obtain the hæmoglobin content of unknown blood samples the corresponding extinction co-efficients are only to be multiplied by the factor 56.0. Table I gives a comparative statement of the values as obtained by this method and the Hellige. Some of the blood samples are anæmic, kindly supplied by Dr. C. R. Das Gupta, of the School of Tropical Medicine, Calcutta.

TABLE I

Hæmoglobin content determined by the Pulfrich photometer and Hellige method with commercially pure sample of benzidine

Serial number	Blood number	HB. CONTENT IN GM. PER 100 C.C.	
		Pulfrich photometer	Hellige method
1	K9	12.9	12.4
2	PP12	9.0	9.4
3	A	4.5	4.8
4	G	9.5	9.4
5	As	7.8	8.0
6	N	12.9	12.9
7	Mn	16.8	16.5
8	ASV	6.2	6.3
9	Md	3.4	3.2
10	BP	9.0	9.2
11	Gk	15.23	12.60
12	CVS	14.10	13.95
13	MNR	15.23	15.00
14	N	12.69	13.60

TABLE II

Hæmoglobin content determined by the Pulfrich photometer and Hellige method with purified sample of benzidine

Serial number	Blood number	HB. CONTENT IN GM. PER 100 C.C.	
		Pulfrich photometer	Hellige method
1	AP	10.8	10.7
2	B	15.6	16.0
3	M	13.2	13.1
4	AD	10.2	10.7
5	BH	7.2	6.9
6	J	5.4	5.5
7	HA	12.0	12.1
8	KCB10	9.0	9.6
9	KCB9	5.4	4.8
10	P	11.4	11.6

The correlation co-efficient of the results of both the experiments is more than 0.9 indicating that commercially pure samples of benzidine may be used for routine purpose. The purified sample may be used for research purposes.

Conclusion

It appears from the above that the method is fairly reliable for hæmoglobin estimation. A few additional points may be mentioned as important.

(i) It has to be noted that none of the usual hæmocytometer fluids which contain sodium sulphate can be used. When these hæmocytometer fluids are added to benzidine, a milky precipitate of benzidine sulphate is formed (precipitation as benzidine sulphate is one of the micro-methods for estimating sulphate).

(ii) This method requires the use of Pulfrich photometer and not an ordinary colorimeter. The colour developed due to the solvent and its impurities is eliminated as a common factor in the Pulfrich photometer by the use of equal sized cells. The unequal column of solution in ordinary colorimeter does not compensate for this.

(iii) The advantage of Pulfrich photometer also lies in the fact that once the extinction co-efficient of the standard solution has been found out one need not use it further for comparison, provided the same reagents are strictly used.

(iv) In addition the use of a correct filter adds to the accuracy.

(v) Much preliminary experience of the technique is required before any reliable results could be obtained.

(vi) Once the preliminaries, i.e. reagents and colour development, are finished a technician can easily test a dozen samples per hour.

Summary

A method has been suggested by which the hæmocytometer fluid left out after use can be utilized for estimating hæmoglobin. This method utilizes the well-known pseudoperoxidase reaction of hæmoglobin. By this method both hæmoglobin estimation and rbc count can be done with as small a sample as one cubic millimetre of blood.

Acknowledgment

THE TOXIC EFFECT OF TEORA (KHESARI) ON MAN

PROTECTION OF THE PUBLIC BY LEGISLATION AND CONVERSION OF TEORA INTO FODDER

By H. JACOBY, M.D.
New Delhi

Introduction.—Preventive medicine occupies a key position to human health. It has on its records the eradication of many epidemic

diseases in vast parts of the globe, viz, smallpox, plague, cholera, etc. But the modern conception of preventive medicine comprises a much wider field than epidemics only. This advancement has found an expression in India for instance in the field of industrial legislation for the protection of labour in factories as laid down in the Indian Factories Act of 1934 or in The Employment of Children Act of 1938. However, the science of preventive medicine does not restrict herself to removing only visible causes of disease, viz, by improving industrial machines with hitherto insufficient protection for the workmen, etc. Its aim is to create such an amount of reserves and power of resistance in man that physical and mental disorders are not only likely to be prevented, but if they still occur, are readily overcome. The attainment of this aim can be achieved by creating the best possible living conditions and healthy surroundings for the individual.

Adequate nutrition is the preliminary to individual health, and initiative and efficiency in industry and agriculture. The absence of good food is an obstacle to the attainment of the best possible level of health and causes well-known deficiency diseases and deficiency conditions in men and livestock. It is therefore one of the most essential concerns of Preventive Medicine and Public Health Authorities to protect the consumer against ill health by the introduction of a legislation for regulation of production, storage, distribution and sale of food based on the science of nutrition. Although poverty is also an important factor in the causation of malnutrition, wise planning on the above lines is apt to reduce its consequences to a minimum. Surely, still more urgent is the problem of nutrition and it is being tackled by government, if a section of the population is forced by circumstances to consume foodstuffs with even toxic action on the human body. Such a dangerous foodstuff is teora (khesari), since its consumption is known to cause lathyrism, a nervous disease with spastic paralysis of the lower extremities, which in the late stages cripples its victims and makes them a burden to themselves and to public funds (see details of this disease in the author's paper on 'Causes, Symptoms and Treatment of Lathyrism' in this journal, February issue, page 53).

Definition of teora.—Teora (synonymous are *khesari*, *matra*, *batra*, *garash*, *Lathyrus sativus*) is a kind of wild vetch, which grows among the weed and other grains and serves in the green and dry state as food for cattle. If produced as an alternative crop to wheat, etc., it is sown in October and harvested in February-March. In times of bad wheat crops and failure of wheat supplies, teora in spite of excessive rainfall and blight, remains uninjured and thrives; its grain is then consumed by men and its stalks and leaves are given to the cattle. Villagers usually consume teora as *chapatis* and the poorer section of the community is in such times reduced to

living almost entirely on teora; sometimes it is consumed mixed with Bengal gram, barley or wheat because the market price of teora grain is the cheapest among all available food grains: its rate was in 1943, 1944 and 1945 only 20 rupees per 5 maunds, whereas the wheat rate was 30 rupees and gram 35 rupees per 5 maunds in the same period (Shourie, 1945).

The toxic agent in teora.—Chemical analysis of the teora grain has been undertaken in India, but so far the chemical formula of a toxin has not been found (from a private communication by the Nutrition Research Laboratories, Coonoor). But since it has been recorded that different outbreaks of lathyrism occurred after consumption of different species of the genus *Lathyrus*, it is obvious that the toxic action is not limited to *Lathyrus sativus* only, but extends to other consumed legumes also, viz, *Lathyrus cicera*, *Lathyrus clymenum* and *Lathyrus odoratus* (see details in the author's paper in this journal). Even animals contracted in experiments a disease similar to lathyrism after feeding on *Lathyrus odoratus*: for instance, rats showed paralysis of limbs, lameness, spinal curvature of the thoracic region (Geiger *et al.*, 1933; Lewis and Esterer, 1943). These experiments on the rat have at the same time shown that the toxic agent, although not defined chemically, is readily extracted from finally ground decorticated *Lathyrus odoratus*, sweet-peas, by cold water, whereas the residue extracted is relatively non-toxic. Geiger found the same to be true by extracting sweet-peas with boiling water. These animal experiments are in accord with the observations by Ranjan (1944) on men, who advises to pour off the water, in which teora is boiled, in order to lessen the toxic effect.

In view of the failure to demonstrate the toxins in teora by chemical analysis, the following reports from Switzerland (Hoffmann, 1946) about a disease following the thrashing of barley and wheat are of great importance. Through inhalation of dust produced by the thrashing of barley or wheat the so-called 'thrash-disease' developed. Mycological examinations of these barley grains, which produce this disease, showed that a toxic fungus grows on and in them. These fungi are probably species of the genus *Alternaria* (fungi imperfecti). Macroscopically it was found that the responsible barley crop had become grey and shrunk after storage in wet surroundings. Also pigs can contract disease if fed on diseased barley. In these experiments another fungus has been found growing on such barley, namely *Gibberella saupinetii*. The pigs vomited such infected barley, lost their appetite, got very weak, and occasionally even died. If wheat-grain is defectively stored it becomes equally grey and causes after consumption a similar disease as the 'thrash-disease'. From such wheat another fungus has been isolated called *Chaetomium* (ascomycetes).

The common feature of all these pathogenic fungi is their growth on such grains only, which after harvesting are lying in the rain for too long, either in the field or afterwards in this wet condition in the barn or in sheds. In one instance, the wheat was standing in the field tied in small sheaves in rainy weather for one week. When eventually the weather is somewhat improved the wheat was spread out in the field for one day. This day was believed by the farmers to be sufficient for drying it and they consequently took it in the evening into the barn. Here it was stored in heaps of 4 m. height. But due to its wet condition and increasing temperature the heap shrank from its original height of 4 m. down to a height of only 3 m.

In view of these findings on wheat and barley grains, the problem of the toxic action of teora appears in a new light. The time after harvesting teora, i.e. after February-March till July, when the fresh teora crop is eaten, is the time of practically no occurrence of lathyrism. But the balance of the crop, which is not consumed before the start of the monsoon in July, is stored and frequently defectively stored. Consequently, during the monsoon it gets wet and we have been informed by witnesses that occasionally very bad smell emanates from freshly opened barns and that such smell often causes even strong men to faint. It is in keeping with all these facts that the outbreaks of lathyrism start in August and are at the peak during September-October when the stored grain is consumed. Because it takes in our experience not more—or probably even less—than a month after consumption of unmixed teora that the disease develops. We see therefore confirmation of our view expressed elsewhere that the toxic effect of teora is probably due to a pathogenic fungus which grows on teora after defective storage in wet condition. This explanation clears up the hitherto incongruous facts of seasonal occurrences of lathyrism and also of the occurrence of the disease in some houses of a village only leaving at the same time other houses out. The storing in the village is done individually by each family and not collectively by the village authorities: hence its defective storage in some houses with the occurrence of lathyrism and its proper storage in other houses without its occurrence.

Preventive measures against the toxic action of teora (khesari) on men.—The following measures are suggested for the protection of the public:—

1. Till we know exactly the nature of the toxin contained during certain seasons in teora and have learned to eliminate it, teora is to be considered a harmful and dangerous foodstuff for men altogether. The public should be prevented from eating it. This can safely and effectively be done only by planning and legislation under the direction of nutrition scientists.

2. Along with this legislation should go an organization of a distribution system for teora

in order to bring it and make it available to fodder-deficit areas, since teora can be turned into a very useful and nutritious foodstuff for cattle.

3. Research to be carried out in a place where teora grows and can be studied on the spot.

Re 1 and 2.—Dangerous drugs like coca leaves, Indian hemp, opium, etc., are controlled by law in the Dangerous Drugs Act, 1920, as amended in 1923, 1925, 1932 and in the Dangerous Drugs Regulations of 1937. Why are dangerous foodstuffs like teora not also controlled by a 'Dangerous Food Act', since teora is no doubt as dangerous for human consumption as the above drugs. The answer may to a certain extent lie in present economic conditions. If men have alternate grains at their disposal, they would certainly prefer these to teora; because these villagers in lathyrism-afflicted areas always seeing before them the crippled condition of their brethren, which has come about after teora consumption, are fully alive to the danger of eating teora. Medical science, though not concerned with the economic aspect of this problem, must, however, point to the necessity of putting alternate grains at the disposal of the people in order to prevent them from eating this toxic stuff. If this requirement is fulfilled, the question arises: What is to be done with the teora crop that thrives without much labour like weeding, even on poor soil, in excess of rain and in hailstorm? Is the cultivation of teora to be prohibited altogether in order to save men from lathyrism? Certainly not, because it is cattle food as well, and the livestock in India described in a recent official report as 'semi-starved' (Pepperall, 1946) requires additional food in many areas.

In times of food scarcity and rationing teora is consumed by the cultivators themselves in order to save wheat in spite of their awareness of the harmful consequences after its consumption. A suggestion for the solution of the problem at this juncture, amenable to all concerned, offers itself: In order to bring back the use of teora to its original purpose, namely cattle food, why not adulterate it to a degree that it becomes unwholesome to man but edible by cattle. Of course, this would require legislation to be introduced and carried out by government. We may suggest the following procedure:—

Government could buy up the whole teora crop and sell it back to cattle-owners at a cheap rate after having carried out the adulteration process. This process will consist of preparing the teora grains with powdered oil-cake (linseed, gingerly, etc.), and plenty of salt. Eventually, the mass will be made out into square cakes. This will be a most nutritious and tasty food for cattle, but men would and could not eat it.

The double advantage of such planning and organization is obvious. Men are given protection against a most fearful and incapacitating

disease; and cattle could get the badly required additional and most nutritional food if transport, distribution and sale at low rates of such teora-oilseed-salt-cakes is well organized by government agencies.

Re 3.—The line of research to be undertaken simultaneously with all the above described practical measures (ad. 1 and 2) is obvious from what is said under the heading 'The Toxic Agent in Teora'. We may only mention the necessity of chemical and mycological investigations on fresh and properly stored and old and defectively stored teora. Once the cause for its toxic action is established beyond doubt, it will be easy to eliminate this cause and to allow teora also to the people as a cheap staple food. Eventually, we may also mention another line of research which should go along with the last mentioned investigations. In the present world food scarcity it is of great interest to know the exact teora percentage in mixtures with other grains so that teora is deprived of its toxic action on men. If we are in the know of this safety margin, it can reasonably be used for stretching the available food resources.

Conclusion and summary

1. Teora (*khesari*, *Lathyrus sativus*) as well as other legumes of the genus *Lathyrus* have the most dangerous toxic effect on man if consumed in a highly concentrated form. They are the causes of the nervous disease 'Lathyrism'.

2. Chemical examinations have up to now not revealed the chemical formula of the toxic agent present in teora. But mycological studies of diseased barley and wheat, which has been stored defectively and has caused the so-called 'thrash-disease' in Switzerland, have shown certain fungi to be responsible for the toxic action of these latter grains.

3. Consumption of teora causes disease only in the months during and following its storage in the monsoon; it is reported by witness that from the barns opened at this time a badly smelling gas emanates. It may therefore be concluded that the toxic effect of teora is due to fungi growing on defectively stored wet teora grains.

4. Until science has established the cause for the toxic action of teora, legislation is suggested to the effect to prevent human consumption of teora.

5. A method is suggested by which teora can be used as a very nutritious cattle food.

6. Suggestions are made for research, which after successful completion, would allow consumption of teora also to man.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIEUTENANT-COLONEL, I.M.S.

Imperial Serologist

and

A. B. ROY CHOWDHURY, M.B.

(From the Imperial Serologist's Laboratory, School of Tropical Medicine, Calcutta)

ADDENDUM TO Rh +/— STATE: CON-GLUTINATION IN DETECTING ANTI-Rh BODY

RECENTLY the importance of a blocking antibody has been revealed. It is an agglutinoid which does not bring about hæmagglutination of rbc suspended in saline, but so sensitizes them that they do not agglutinate on the addition of a standard human anti-Rh serum later. Instead of being an ineffective hæmagglutinin it is a very potent hæmolytic agent in the presence of human serum.

Its presence is detected thus: The rbc under test are suspended in the serum of the subject himself or the serum of a subject AB. On the addition of a serum containing the blocking antibody hæmagglutination develops in the usual way on slides and in tubes. This is conglutination.

The easiest way to suspend the subject's rbc in his own serum is as follows: After removing the clear serum from the clot (in the tube intended for preparing serum) 'incise the clot and shake the tube. Serum turbid with rbc will ooze out. Separate the turbid serum in a small tube (Durham tube). Match the turbid serum with a standard 2 per cent rbc suspension. Add more of clear serum to reduce turbidity if necessary. The turbid serum now is a 2 per cent suspension of the subject's rbc in his own serum.

For transfusions in all maternity cases and for second or subsequent transfusions in all cases, the donor's rbc suspended in his own serum must be put up with the recipient's serum, in cross-matching, i.e. a conglutination test must be done.

This method is preferable to the use of whole blood in cross-matching. The whole blood under certain conditions coagulates and produces the appearance of hæmagglutination.

PRECIPITIN REACTION

An antigen in solution, after a parenteral entry into an animal, gives rise to an antibody which when brought into contact with it *in vitro* (in glass, in a test tube, etc.) produces a precipitate. The antibody is the precipitin. The reaction is the precipitin reaction. The precipitate is mostly the altered antibody, unlike the product of agglutination which is mostly the altered antigen.

For all practical purposes the antibody is kept constant (usually undiluted antiserum) and the antigen dilution varied to obtain this titre of the antibody. If an undiluted antihuman serum, for instance, produces a precipitate with a 1 in 20,000 dilution of human serum, it has a titre of 1 in 20,000.

The precipitin reaction is employed routinely in tracing the source of blood, for medico-legal purposes, in blood stains. It can also be used for differentiating between flesh foods such as beef and mutton.

Another important application of the reaction is found in determining the potency of antitoxins which produce precipitates with their toxins. In toxin antitoxin reaction the antibody is not kept constant always.

The flocculation reactions for syphilis are also precipitin reactions. In the Kahn test the antibody is the syphilis reagin in the human serum which produces a precipitate with the Kahn antigen.

(Reagins for many purposes behave like antibodies. The Kahn antigen is a non-specific reagent which happens to fit into a reagin. The Wassermann antigen, also a non-specific reagent, fits into the reagin in the same way in the complement fixation reaction for syphilis usually known as the Wassermann reaction.)

THE PRECIPITIN RING TEST FOR DETERMINING THE SOURCE OF BLOOD PROTEIN

In this test an extract in normal saline (sodium chloride 0.85 per cent) of the unknown stain, of the order of 1 in 1,000 dilution of the original serum in the stain, is superimposed on small quantities of known undiluted antisera. A ring of white precipitate develops at the junction of the two fluids with the appropriate antiserum. The ring is almost entirely in the antiserum.

The antisera are tested for stability, sensitivity and specificity immediately before use.

The special apparatus consists of only: (1) Tapering tubes made in the laboratory. (2) Light wooden racks holding in a single row twelve tubes. The tubes pass through two perforated shelves and rest on the bottom shelf which is without depressions and painted dull black. The racks are numbered on the left hand extremity. One should be able to examine a full rack in $\frac{1}{2}$ minute.

Preparation of the antihuman precipitin serum.—Fresh pooled serum from at least six healthy donors of blood is filtered through Seitz filter and inactivated at 56°C. for half an hour. If the donors are not available a selection is made from sera left over from the various blood tests which a serological laboratory also undertakes to perform. 3 c.c. are given intravenously to fowls which have been observed for a week to exclude disease. The serum protein is the antigen. Ten days later the fowls, after being kept on water only for 24 hours (otherwise the

serum will be chylous), are anaesthetized with ether and bled to death. Each fowl yields about 20 c.c. of blood which yields about 10 c.c. of serum. The serum is separated, tested for stability, sensitiveness and specificity, and stored frozen, if found suitable. The substance produced in the serum as a result of the injection of the antigen is the antibody. In the reaction the antibody is precipitated by the antigen: Hence the use of undiluted antisera.

The serum is stable if it does not become opalescent in a 1 in 5 dilution in normal saline.

The stable serum is sensitive if it reacts with human serum (1) in a 1 in 1,000 dilution, within 2 minutes *frankly*, +, and within 10 minutes *sharply*, ++; (2) in a 1 in 20,000 dilution, in 10 minutes *dubiously*, ±, and in 20 minutes *frankly*, +; and (3) in a 1 in 40,000 dilution in 20 minutes *dubiously*, ±. Otherwise the serum is either not sensitive enough and is discarded, or is too sensitive (when a 1 in 1,000 dilution reacts sharply instead of frankly in 2 minutes and a 1 in 40,000 dilution reacts frankly instead of dubiously in 20 minutes) and stored (in the cold, but unfrozen) for ageing and retesting.

The sensitive serum is specific if it does not react with (1) buffalo's serum 1 in 1,000, (2) dog's serum 1 in 1,000, (3) horse's serum 1 in 1,000, (4) fowl's serum 1 in 1,000, (5) sheep's serum 1 in 1,000, (6) an extract from dried stain of monkey's blood made to correspond to a 1 in 1,000 dilution at least (may err towards 1 in 500) of human serum by comparison of froth (*vide infra*). Quite a large number of sensitive sera react non-specifically, mostly with dog's serum. They are stored unfrozen for ageing and retested. If still unspecific they are rejected.

For use a frozen serum is left to thaw in the refrigerator overnight before it is exposed to room temperature. It is retested for stability, sensitiveness and specificity before use.

Preparation of other antisera.—Antisera for blood of other animals are prepared along similar lines. Antifowl serum is prepared in rabbits. The serum is taken from a single healthy animal. Its titre is less than that of sera prepared in fowls. It reacts with blood of all birds.

The number of antihorse sera reacting non-specifically is even greater than that of antihuman sera so reacting.

Extracts from stain: 1. *Stains on cloth.*—Of a good stain an area about 1 cm. in diameter is cut out and extracted with about 2 c.c. of normal saline in a test tube at room temperature for half an hour, *without shaking* (otherwise opalescence may appear). Less than half of the extract is transferred gently to another test tube, diluted with 1 to 3 c.c. of normal saline and frothed by hitting the tube against the palm of the hand. The froth is matched with that of a known 1 in 1,000 dilution of human serum, the standard. If the froth is thicker more saline is added. This is the adjustment of the serum

content by *foam test*, by equalizing the froth index (the use of two terms denoting the same mass of bubbles is regrettable). The froth may be slightly thinner but not thicker than that of the standard.

From a poor stain as much of the stain and as little of the cloth as possible is cut out for extraction.

When an extract yields poor foam the fact should be recorded on the tube together with the reason, e.g. $Fm \pm$, $Fm \pm s$ (because of small stain), $Fm -$ or $Fm -s$. This record is important in the interpretation of results (*vide infra*).

Prolonged soaking of the stain in the cold does not render insoluble stains soluble for the purpose of the serological test. The prolonged soaking recommended for crevices and joints of weapons aims only at the entry of the normal saline.

The extracts should not be opalescent. The opalescence may be removed by centrifuging at high speed or by adsorbing the extract to a filter paper, drying and re-dissolving. If it cannot be removed the exhibit must be rejected.

2. *Stains on other objects.*—The stain is scraped or washed off as appears suitable. Extraneous matter (such as vegetable matter from wood, twigs, etc., and underlying stains from weapons) should be excluded if possible. From stained earth as little of the stained material as possible should be taken. The froth index is adjusted as before. Prolonged soaking may actually interfere with the test because of (i) earth, etc., rendering the protein in the extract inert by prolonged contact with it in the presence of water and (ii) tannin, etc., going into solution and later precipitating the antiserum.

The stain selected for the extract should be free from previous chemical treatment. If a stain is very small an extract should be prepared from the whole of it first, and the chemical and spectroscopic tests applied to the residue afterwards. The tests are obligatory.

Technique for human blood: The extract from the stain.—(1) A fraction is put into a tapering tube to yield a column about $1\frac{1}{2}$ cm. high. The tube is tilted once almost 90° , to wet a small surface on one side and above the column, and then held at 45° . On the wet surface is deposited from a pipette with a capillary point enough antiserum to sink down the side of the tube and occupy about $\frac{1}{3}$ to $\frac{1}{2}$ cm. of the bottom with the tube in vertical position. The tube is made vertical again gradually. The extract is now superimposed on the antiserum. This is the test proper. (2) Another fraction is put into another tapering tube and superimposed on normal fowl serum. This is a control with the normal fowl serum. (3) When the unstained part of the exhibit is not available, yet another fraction is superimposed on anti-horse serum. This is a control with a second antiserum. The extract though without effect

on normal fowl serum may precipitate the heavier antiserum because of organic or inorganic chemicals in the cloth. In the absence of horse's blood (excluded by the facts of the case) this control should yield a negative result.

2. *The extract from the unstained part of the exhibit.*—This is also superimposed on the antiserum. This is the unstained control. For testing stains on articles of dress this control is indispensable, as beside organic and inorganic chemicals in the cloth reacting non-specifically, sweat and other animal matter may also react specifically with the antiserum. It is not likely that clothes of the accused will be so drenched with blood as not to leave an unstained area available. If that really be so an unstained area from known clothes of the accused should be provided as a control of the sweat and animal matter. The latter definitely interferes with the determination of blood group from stain.

The controls are put up and examined first. There should be no ring in 30 minutes. In the test proper the positive reaction is indicated by a ring appearing within 10 minutes and becoming at least frank if not sharp in 20 minutes. Earth mixed with blood delays the reaction: special observation is then necessary of all the controls (including those of the specificity of the antiserum) for 30 minutes.

When a reaction of almost the same intensity, within almost the same time, appears both in the controls and the test proper, further attempts at obtaining results are not made. But when the reaction in the controls is much weaker than the one in the test proper, the extracts are diluted and retested, ensuring that the extracts from the unstained part is not diluted more than the one from the stained part.

In the routine, when many tubes are under examination, racks are so filled and manipulated that every tube is examined within 10 minutes, 20 minutes and 30 minutes (if necessary).

Examination: (1) The tubes are examined in the racks within 10 minutes and left in their places if ++ or +. (2) If \pm within 10 minutes, they are transferred to the left of another rack and re-examined after 20 minutes. A + in the place of the former \pm will be accepted. (3) If negative within 10 minutes, they are transferred to the right of the other rack and re-examined after 20 minutes. Probably they will remain negative. If they turn +, the reaction will not be accepted without reference to the nature of the specimen and without repetition with concentrated extracts.

Technique for other animal's blood.—Instead of the antihuman serum other appropriate antisera are used. In the case of the antifowl serum, the serum control is put up with normal rabbit serum. When an extract of good quality is negative with antihuman sera, it is tested routinely with antisheep and antifowl sera.

Group reaction: 1. *Man and monkey.*—Fresh monkey's blood (serum) reacts with the antihuman serum almost like the human serum.

But the extract from dried monkey's bloodstains does not react in a 1 in 1,000 dilution as prepared by comparing the froth index.

2. *Buffalo and cow.*—The above technique does not differentiate between the blood of these two animals.

3. *Sheep and goat.*—The technique also fails in the case of these animals.

4. *Buffalo or cow and sheep or goat.*—The difference between the two groups can be made out easily by testing with antibuffalo and anti-sheep sera of equal potency. The group reaction appears earlier. Further, by serial dilutions a stage is reached when the extract reacts with one antiserum only.

Preparation of antihare serum in rabbits and antirabbit serum in hares has been reported in the past. It has not been repeated recently. Absorption of a group antiserum by one member's blood does not leave the required residue.

Antisera for detecting other animal's blood.—Only the antisera mentioned so far and the anti-monkey serum are kept in the Imperial Serologist's Laboratory. Any other antiserum, if required, can be prepared within a month or so.

pH of the extract.—The range for a successful serological reaction being pH 4.5 to 9.5 can be tested even with litmus paper. As a routine small strips of blue and red litmus paper are put into the balance of the extract after its serological reaction has been recorded. A certain degree of acidity which does not destroy the reaction is known to give a false positive reaction. Similarly a certain degree of alkalinity which does not destroy the reaction is known to give a false negative reaction. Usually all extracts are found to be neutral.

More than one blood in a stain.—When an extract with a good froth gives with antihuman serum only a frank or even a dubious reaction, it should also be tested with antishcep and antifowl sera routinely. Several bloods dilute each other although the froth index given by the total serum protein is good. A frank reaction must be obtained after concentrating the extract and excluding group reaction.

Feeble reaction of some coloured extracts with good froth.—Such extracts are derived from clots from which serum has drained away. The hæmoglobin imparts colour and certain amount of froth to the extract the serum-protein content of which remains poor: hence the feeble reaction. The extract should be concentrated to correspond to a 1 in 500 serum dilution and also tested with antifowl, antishcep, antihorse and antimonkey sera when it is being tested for human blood.

The hæmoglobin of an animal, although a protein, does not react with the antiserum prepared against its blood serum.

Substances responsible for a false positive reaction.—The following common substances if present in the extract precipitate the antiserum and thus produce the semblance of a positive

reaction: (1) Soap. This is of special importance in *washed* stains. (2) Rancid oil such as found sometimes on pillow cases and head dresses. The soluble fraction of the oil prevents frothing yet the extract gives sharp and quick reaction. The oil can be removed by immersion of the stain in ether. (3) Alum. This is used as a household remedy in gargles and mouth washes and may stain any article. (4) Tannin and allied substances are derived from vegetable tissue. The stain of the saliva of the betel chewer not only looks like a bloodstain but by virtue of the tannin present in most of the constituents of the prepared betel also acts on the antisera. Stains on leather and plant tissue should be removed by applying moist filter paper to the surface. (Leather contains tannin.)

Substances responsible for a false negative reaction.—Mineral acids, corrosive sublimate, chloride of lime, sulphate of copper and iron, bisulphide of carbon and sodium, nitrate of silver, thymol and permanganate of potassium abolish the reaction.

Tropical influences.—Some stains become insoluble within a few months. Putrefaction of wet stains weakens and destroys their serological reactions.

Results other than positive: 1. *Disintegrated.*—Stains are reported disintegrated: (1) When stains of poor quality (foam \pm or $-$) react chemically but not serologically. (2) When under standard conditions frank rings are not obtained with the routinely used antisera. This is done even though all sources (e.g. fish, frog and snake) are not exhausted. (3) When poor extracts (foam \pm or $-$) give sharp rings and/or react quickly. The extract from the unstained part of the exhibit also acts in such cases. Probably chemicals are present in the fabric. A $Fm \pm s$ or $Fm - s$ extract giving a frank reaction which is not quick is accepted as positive. (4) When rich extracts give weak reactions (e.g. dubious reaction just turning frank in 20 minutes, instead of being sharp in 10 minutes) and the possible interferences have been excluded (*i*, more than one blood; *ii*, excess of hæmoglobin; *iii*, presence of earth). (5) When anomalous reactions occur. This category includes the lack of correspondence between the controls and the departure from the normal of the size (*i*, very thin; *ii*, very thick, *iii*, more than one) and shape (*i*, broken periphery of the disc; *ii*, honeycombed mass of precipitate; *iii*, conical or spherical surfaces) of the ring.

2. *Negative.*—Exhibits stained with blood of good quality but not giving the reaction of human blood are reported 'Not stained with human blood (or any other blood specified in the requisition)' or 'Stained with the blood of a ruminant animal or a bird (as the case may be)'.

3. *Such reaction that no opinion is possible.*—Occasionally, an extract, on concentration, reacts with several antisera to almost the same degree and against expectations. This category differs from 1(5) in not being so obviously anomalous.

Possibly mammalian and group reactions interfere due to concentration.

Tests for animal tissues.—The precipitin test will determine the source of tissues like muscle, bone, skin, etc., if their identity as tissues can be determined histologically. The material for the extract is taken from the inside of the object with a view to avoiding the reaction of the superimposed blood. Previous application of heat (as in cooking and partial cremation) renders the serum protein insoluble and weakens or destroys the reaction. An attempt should be made with all but charred remains.

Tests for stains of animal origin, other than bloodstains.—These stains in order of their importance are: 1, seminal stains, 2, faecal stains, 3, salivary stains, 4, urinary stains and 5, sweat stains. Only the origin of a seminal stain can be determined, like that of a bloodstain, after its nature has been determined by finding spermatozoa and blood excluded chemically and spectroscopically. The nature and therefore the source of the rest cannot be determined.

(To be continued)

LOCAL TREATMENT OF INFECTED EXPERIMENTAL WOUNDS*

By B. V. PATEL

(Haffkine Institute, Bombay)

DANN, GLUCKSMANN and TANSLEY (1942) tried cod-liver oil and its various fractions in the treatment of experimental wound in rats. They found that cod-liver oil acts as a mild irritant, which perhaps benefits healing by stimulating the formation of granulation tissue.

Sulphonamides have been used very widely both locally and internally for the treatment of infected wounds. The clinical progress of most of the cases has been satisfactory and healing occurred rapidly. In the course of investigations on control of sepsis in war wounds, Dikshit and Gardham (1945) found it desirable to have a 'water-in-oil' type of emulsion for making sulphanilamide paste, so that the absorption from the site of application may be slow, and at the same time a high concentration be maintained near the wound. The local treatment is preferable to internal drug treatment, as it has the advantage of precluding the danger of severe toxic effects of the drug.

This paper reports the results of investigations made with pastes made with the following formula using six different sulphonamides, namely, sulphasuxidine, sulphadiazine, sulphaguanidine, sulphamethiazine, sulphanilamide and sulphathiazole.

Sulpha drug	12 g.
Calcium oleate	3 g.
Bees wax	3 g.
Cod-liver oil	60 c.c.
Water	40 c.c.

Method of preparation.—The ingredients are sterilized individually and the paste made under aseptic technique. Calcium oleate is first rubbed with a small quantity of cod-liver oil in a mortar, and then the sulpha drug is incorporated. Bees wax is heated with cod-liver oil to a temperature of 80°C., poured into a mortar and constantly stirred. Boiling water is then added and stirring continued till the temperature of the paste comes down to 37°C. This paste is then filled into sterile collapsible tubes.

Treatment of wounds in rabbits.—Rabbit was used as the experimental animal for this investigation. Circular wounds, 2 cm. in diameter, were made on the shaved back of the rabbit by incising the skin with several 'criss-cross' incisions. Bleeding points were touched with hæmostats and the wounds were infected with a drop of a suspension of mixed culture of *Streptococcus hæmolyticus*, *Staphylococcus aureus* and *Bacillus pyocyaneus*. Four wounds were made on each rabbit and after infection three were treated by the application of paste and covered with a piece of lint which was kept in position by adhesive plaster. Each rabbit had one wound which was not treated and covered only with lint. These rabbits were examined every third day and redressed. The results of all the experiments have been summarized in table I.

This shows that of all the six drugs, sulphathiazole produced the best results, since the discharge was much less, pus cell formation and the growth of cocci were arrested on the 8th day, and healing began earlier and was complete on the 11th day. Sulphadiazine was the next best, because discharge and pus cell formation were less and the edges of the wound were clean and soft. Sulphanilamide showed good but slow healing, i.e. complete healing on the 15th day.

Concentration of the drug.—In order to determine the maximum concentration reached due to local application, the drug in the form of emulsion was injected into the muscles of the flank using a lumbar puncture needle. 2 c.c. of the paste were injected in each case and samples of blood were collected at the end of 1, 4 and 24 hours. The concentration of the free drugs in the samples of blood was determined by the method of Bratton and Marshall (1939). The concentrations of the free drug reached are given in table II.

Discussion

The investigations bring out two main points. Firstly, the concentration of the drug, in any case, does not go high except in the case of

* Read before the Indian Science Congress Session held at Bangalore in January 1946.

TABLE I

Drugs	3rd day	6th day	8th day	11th day	REMARKS
Sulphasuxidine ..	D + P - H No signs of healing. O + +	D + P + H Healing begun. O + +	D + P + H Half healed O ++ -	D ± P + H Three-fourth healed. O + +	Healing slow although discharge is less.
Sulphadiazine ..	D + P - H No signs of healing. O + +	D + P - H Healing begun. O + +	D ± P + H Half healed O + +	D ± P ± H Almost healed. O + +	Rings round the edges soft. Discharge comparatively less.
Sulphaguanidine	D - P - H No signs of healing. O + +	D - P + H Healing begun. O + +	D + P + H One-third healed. O ++ -	D + P + H Half healed O + +	Vascular reaction around the wound very marked. Hard ring round the edges.
Sulphamethiazine	D - P - H No signs of healing. O + ++	D + P + H Healing begun. O + ++	D + P + H One-third healed. O + ++	D - P + H Half healed O + +	Wounds showed clean edges. Margin elevated.
Sulphanilamide ..	D + P - H Shows signs of healing. O + -	D + P + H One-fourth healed. O + +	D + P + H Half healed O + +	D ± P + H Three-fourth healed. O + +	Hard ring round the edges.
Sulphathiazole ..	D - P - H Shows signs of healing. O + +	D + P + H Half healed O + +	D ± P ± H Three-fourth healed. O - ±	D - P - H Completely healed. O - -	Ring round the edges soft. Discharge much less.
Control ..	D + P - H No signs of healing. O ++ ++	D + P + H Healing begun. O ++ ++	D + P + H One-third healed. O ++ ++	D + P + H Half healed O ++ ++	Hard ring round the edges. Hard scum formed.

D = Discharge. P = Pus cells. H = Healing. O = Organisms. (*Cocci, B. pyocyaneus*.)

TABLE II

Drugs	CONCENTRATION IN MG. PER CENT		
	1 hour	4 hours	24 hours
Sulphasuxidine ..	1.49	0.50	0.17
Sulphadiazine ..	0.98	1.23	0.81
Sulphaguanidine	1.05	1.05	0.34
Sulphamethiazine	0.82	0.68	0.69
Sulphanilamide ..	3.65	6.00	0.43
Sulphathiazole ..	0.83	0.75	0.30

sulphanilamide. Secondly, sulphathiazole was found to be the best of the sulphonamides. Hawking (1941) has shown that sulphonamide applied locally penetrates only a few millimetres

into the infected tissue and, therefore, may not reach viable bacteria. It seems probable, however, that provided the bacteria in the necrotic tissue and exudate, which is the actual culture medium, are destroyed the deeper granulating zone with its own capacity for combating infection is easily capable of overcoming the deeper infection. The rapid development of healthy granulating tissue actually observed during this treatment suggests that the reduction in the number of organisms in the surface exudate allows this tissue to rapidly assume its normal protective function.

A Mirror of Hospital Practice

PARKINSONISM IN TYPHOID FEVER

By P. N. LAHA, M.D. (Patna)

Medical College, Agra (U. P.)

PARKINSONISM may be the end-result of paralysis agitans, encephalitis lethargica, arterio-sclerosis, poisoning with manganese and carbon monoxide, trauma, syphilis and hepato-lenticular degeneration. Horder (1946) describes having seen a condition indistinguishable from paralysis agitans follow a severe attack of influenza, which ended in complete recovery after several months.

Below is recorded a case of typhoid fever in whom Parkinsonism developed as a complication. Such a complication is very unusual and as such worthy of publication.

Case report

J., 19 years, Hindu male, was admitted into the hospital with the complaint of high continued fever, duration 15 days. There was history of discharge of pus from the right ear, duration 10 years. Before the attack of fever patient got severe right-sided ear-ache with profuse discharge of pus. Four days later he had frontal headache and fever. After another 4 days he became semi-comatose with facial paralysis on the right side.

On examination the patient looked acutely ill; temperature 101°F.; pulse 90, respirations 22, per minute; blood pressure 85/45. There was masklike facies with exceptionally greasy skin and right-sided infranuclear facial paralysis. Neck and trunk were markedly rigid. Kernig's and Brudzinski's signs were strongly positive. The extremities were rigid, flexed and adducted. Tendon jerks were diminished. Sensations could not be tested accurately. Abdominal reflex was intact in all quadrants. Babinski's sign was flexor on both sides. There was no tremor anywhere. Other symptoms were normal.

Investigations.—Fundi normal. Cerebro-spinal fluid 20 ml. was drawn out under high tension by lumbar puncture; a few monocytes were found; protein 1.2 per cent, sugar nil, and chloride 775 mg. per 100 ml.; no micro-organisms. Total white cells 14,000 (polymorphonuclears 59 per cent, lymphocytes 41 per cent; no parasites). Blood culture—*B. typhosus* was isolated. Widal test (on 18th day of fever) was positive against *B. typhosus* 'H' up to 1/640 dilution. Urine and stool normal. Wassermann reaction negative.

Progress and treatment.—He was put on usual treatment for typhoid. After 31 days he gradually became afebrile. After another

fortnight his Parkinsonism disappeared completely. The discharge of pus from his right ear was controlled but the facial paralysis persisted.

Discussion.—It was a frank case of typhoid fever with Parkinsonism as a complication. Parkinsonism was the result of inflammatory involvement of either the corpus striatum or the substantia nigra. The inflammation gradually subsided and along with it the Parkinsonism disappeared. Absence of tremor could be explained by the fact that rigidity was very marked, for there is an antagonism between the tremor and rigidity of Parkinsonism. The facial paralysis was evidently a complication of otitis media.

Acknowledgments

My thanks are due to Major-General H. C. Buckley, C.S.I., I.M.S., Principal, Medical College, Agra, for his kind permission to publish this report and also to my colleagues of the Pathology and Biochemistry Departments for their valuable help in investigating the case, also to Drs. R. P. Singh and H. Prasad, who helped me in treating the case.

Therapeutic Notes

NOTES ON SOME REMEDIES

VII. SULPHONAMIDES

III

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.), T.D.D. (Wales), F.S.M.F.

Professor of Tropical Medicine, School of Tropical Medicine, Calcutta

6. *Urinary tract infections.*—In acute cystitis and pyelitis and in chronic infection due to coli bacilli sulphanilamide is adequate but sulphacetamide has been particularly recommended because of its high solubility in urine. Its sodium salt (albuclid soluble) may be injected intravenously in 30 per cent solution. Sulphathiazole or sulphadiazine may be given in resistant cases. The average daily dose is 3 gm. given in doses of 0.5 gm. four hourly, but during the first day 5 to 6 gm. may be given in order to bring about a rapid rise in the concentration. Fluid intake should be 5 pints daily to ensure a urinary output of at least 2 pints. The drug is more effective if combined with alkaline diuretics, so along with it a mixture of sufficient sodium citrate and sodium bicarbonate should be given to render the urine alkaline. With this treatment, pain, pyuria and albuminuria disappear more rapidly than with alkalies alone. After a

few days the urine should be re-examined to see if there has been relapse, in which case the treatment is repeated but this indicates the need for careful urological investigation. Infections due to *Staphylococcus aureus*, *Ps. pyocyaneus* and *B. proteus* are less sensitive, while *Streptococcus faecalis* is resistant to sulphonamide therapy. Mandelic acid treatment may be tried for obstinate relapses or when the organisms are resistant.

7. *Veneral diseases*.—The treatment of gonorrhoea has now been greatly simplified. Large initial doses are not required nor is it necessary to have a high blood level. The more effective drugs are sulphathiazole and sulphadiazine. A dose of 5 gm. distributed evenly over 24 hours and taken for five days is usually sufficient in uncomplicated cases. If it is not convenient to wake up at night, 1 gm. (2 tablets) should be taken at bed time and another similar dose on getting up from bed. Local treatment with irrigation is usually unnecessary. A small percentage of cases are resistant to the drug and are best treated with penicillin. More often the failure to respond to sulphonamide is due to extension of the disease to posterior urethra, prostatitis, etc. In such cases the treatment is given up to seven days and then after a week it is repeated, preferably with a different drug and accompanied by local irrigations. In the interval between the two courses some workers prefer to give intramuscular injections of a non-specific protein preparation such as sterile milk (2 to 5 c.c.); two such injections are given during the week.

The incidence of complications has been much reduced by chemotherapy; this is materially helped by proper rest and administration of the drug at a very early stage. The majority of complications respond readily to sulphathiazole in adequate dosage, but if there is an enclosed focus of infection, it is usually necessary to secure free drainage by local treatment. The drug is often disappointing in acute arthritis and tenosynovitis and seldom of value in chronic arthritis. Chemotherapy does not obviate the need for keeping the patient under observation up to three months before he is declared free from infection.

In the female chemotherapy is equally successful. Good results have also been obtained in ophthalmia neonatorum; full dosage should be given; after an initial dose of 0.25 gm. the drug is continued in 0.125 gm. ($\frac{1}{4}$ tablet) doses six hourly for five days. Local treatment by gentle irrigation with saline is seldom necessary after the first day. Rapid recovery however follows the instillation of eye drops of penicillin solution containing 500 units per c.c. repeated every two hours. Corneal ulceration responds rapidly and seldom occurs after chemotherapy has been begun. When it is present, 1 per cent atropine sulphate should be instilled into the eye.

For *chancroid*, sulphanilamide or sulphathiazole is given in a dosage of 5 gm. a day for

seven to ten days. The results are usually very good. Some cases are however resistant and these may be treated with dmelcos vaccine. The local sore is washed twice a day with warm saline and dusted with sulphanilamide powder. In patients with tight phimosis and underlying ulcerative lesions, the preputial cavity is irrigated with potassium permanganate solution, but healing is sometimes delayed and it may be necessary to secure free drainage of the ulcers by a small operation. Buboec should not be incised if possible but may require aspiration. In early cases of *Lymphogranuloma inguinale* the response is good. A dose of 25 to 30 gm. by mouth is given in five to seven days, repeated, if necessary, after a brief respite. In the majority of cases there is speedy resolution of the lesion. In resistant cases this treatment may be followed by non-protein shock given by a series of T.A.B. or dmelcos vaccine.

8. *Peritonitis*.—Sulphonamide therapy has been extensively employed as an adjunct to surgical treatment in peritoneal infection due to appendicitis, perforated peptic ulcer, etc., or where the peritoneal cavity has been soiled by trauma or at operation. Sulphanilamide, sulphathiazole or sulphadiazine is used; the latter has the advantage of being slowly absorbed and so its action lasts longer than the other two drugs. The dosage depends on the amount of contamination present. It is best applied as a fresh suspension (previously autoclaved at 20 lb. pressure for 20 minutes) of 10 to 20 gm. of the powder in 4 to 10 ounces of saline warmed to body temperature. After removal of any free pus as far as possible, the suspension is squirted into the abdomen as a fine jet from a record syringe without a needle and part of it is applied to the edges and layers of the wound after closing the peritoneum. Supplementary chemotherapy by mouth or injection might improve results if peritonitis is already established or associated with a blood infection; it should not be begun until after 48 hours when blood concentration from the intraperitoneal application begins to fall. Sterile sulphanilamide powder can be dusted in the abdominal cavity as a prophylactic after operation for perforated peptic ulcer, removal of infected fallopian tube, etc.

9. *Wounds*.—Opinion is not unanimous on the value of sulphonamides and they are better reserved for obvious contaminated wounds. Much depends on such factors as presence of dead tissue and sloughs, degree of contamination and the time that has elapsed before the treatment. The sulphonamides are certainly helpful in controlling the infection, particularly by hæmolytic streptococci and preventing its spread, but success depends first and foremost on adequate primary surgery, and care must be taken that the drug reaches the depths of the wound. Sulphanilamide can be used locally, but a mixture of the drug (3 parts) and sulphathiazole (1 part) maintains the concentration for

a longer time. Another combination which is specially effective in infections caused by gram-positive and gram-negative organisms is a powder containing 1 part of proflavine and 99 parts of sulphathiazole. This powder is a little irritating to the tissues and should be applied sparingly; the treatment is repeated at two-day intervals, if necessary, but not more than three such applications should be made. Whichever powder is used it should be sterilized and kept in a sterile container. It is insufflated in a thin film over the raw surface not exceeding 10 gm. at any application. Sulphonamides should not be applied in the immediate neighbourhood of important nerve trunks and only sparingly to wounds involving the brain; sulphathiazole in particular should never be applied to the brain as being likely to cause epileptiform convulsions. When there is great risk of septic infection, a course of sulphathiazole by mouth seems to be of definite value, the dose being reduced owing to absorption of the drug locally applied (approximately this gives in the first six hours 0.5 mg. per 100 c.c. of blood for each 1 gm. of the compound and thereafter the concentration rapidly falls). The first dose should be 2 gm. and then 0.5 gm. at four-hourly intervals for four days. Shock and hæmorrhage are not contra-indications to their use, but precautions must be taken against renal complications. An essential part of treatment of any large wound is adequate splinting.

It is unwise to apply sulphonamides repeatedly to wounds which are healing satisfactorily, but, in the later stages, their local use may be valuable when healing by granulation tissue is retarded by the presence of streptococci.

In the local application to wounds, penicillin has many advantages over sulphonamides, but the two are quite compatible and they can be conveniently combined in powder form.

10. *Burns*.—The primary aim in the treatment of burns should be to avoid infection and this is made possible by the inhibition of bacterial growth which results from the local application of sulphonamides. In ordinary circumstances, a patient with severe or extensive burn should be immediately removed to hospital without any attempt to give first aid beyond keeping him warm and giving morphine if need be, but when superficial burns are treated at home or when larger burns cannot receive proper treatment without considerable delay, they may be smeared under aseptic conditions with a water soluble cream containing 1 per cent 'cetavlon' and 3 per cent sulphanilamide and carefully wrapped in sterile lint and a bandage. The cream should be removed within two days because of a slight risk to dermatitis by cetavlon, and replaced by the mixed cream mentioned below.

If the patient is suffering from shock, local treatment is confined to application of a first aid dressing only. The shock is treated first and complete cleansing and dressing are postponed till the second or third day when the blisters are

carefully removed, and the burnt area is cleaned with soap and water, or better with 1 per cent cetavlon solution. A mixed sulphonamide cream such as the following is then applied: sulphanilamide 3 gm., sulphathiazole 3 gm., glycerine 10 gm., castor oil 25 gm., lanette wax sx 10 gm. and water 49 gm. The burn, which must be widely covered and firmly bandaged, is left untouched for seven to ten days unless the affected part is such that contamination is unavoidable. A little fever (up to 102°F.) is in itself no indication for changing the dressing. On removal of dressing, many second-degree burns will be found to have healed, but the cream may be reapplied for a further week if necessary. This treatment is effective in a large proportion of cases, but in some the hæmolytic streptococcus is able to establish itself from lack of aseptic and antiseptic precautions. It is therefore most necessary to observe a high standard of technique for dressing. Streptococcal infection of burns which are resistant to sulphonamides may respond to penicillin or to propamidine.

11. *Miscellaneous infections*.—(1) *Anthrax*: The sulphonamides are a safe and reliable substitute for anti-anthrax serum. Sulphathiazole is recommended, but if there is no response in three days the serum is indicated.

(2) *Brucella infections (Undulant fever)*.—Reports are conflicting and the sulphonamides are still being tried. Chaudhuri and Rai Chaudhuri (1943) reported a case in whom sulphapyridine and sulphathiazole were used; both had a more or less immediate action in controlling fever but not the subsequent bout of fever. Probably the dosage was not sufficient. Manson-Bahr (1945) recommends large doses, and for prolonged periods, 4 to 9 gm. daily for courses of four to five days each.

(3) *Diseases and injuries of the eye*.—Sodium sulphacetamide is valuable in many of these cases. *Blepharitis*: an ointment containing 2.5 to 10 per cent of this drug or 5 per cent sulphathiazole is applied 1 to 4 times daily, or where an ointment is unsuitable, a 10 to 30 per cent solution of sodium sulphacetamide may be painted along the roots of the lashes. *Conjunctivitis*: A 10 per cent solution is instilled two hourly in acute condition and a 2.5 per cent solution is instilled in less acute conditions. *Corneal ulcers*: A 10 to 30 per cent solution is instilled several times a day. *Trachoma*: The action seems to be not on the virus but on the secondary infections so often associated with trachoma. Dramatic alleviation of distressing symptoms such as photophobia can be produced. Sulphanilamide has been recommended (1) in a daily dose of 2.0 gm. and (2) as a local application in saturated solution several times a day. This is given for ten days followed by ten days' rest, and then a second course for ten days is given. As a prophylactic against infection after injuries and burns, several drops of a 10 per cent solution of sodium sulphacetamide are instilled as soon as possible.

(4) *Plague*.—The most important single factor which decides the issue in human bubonic plague is the development and degree of septicaemia. The sulphonamides are the best drugs at present available in the treatment of this disease. If they are given early, septicaemia seldom develops, and when this is present, they give far better results than any other treatment. Sokhey and Wagle (1946) recommend sulphathiazole to start with an initial dose of 2 gm. followed by a similar dose after four hours and then 1.5 gm. four hourly during the first 24 hours. It is then continued in one gramme dose four hourly and is stopped two days after the temperature comes to normal and the patient's general condition improves. Anti-plague serum with sulphathiazole, according to these authors, seems to easily bring the toxæmia under control. They found even better results with sulphadiazine but the number of cases treated with it has not been large enough. This drug is given with an initial dose of 4 gm. followed by 2 gm. four hours later and then 1 gm. four hourly. Neither of the two drugs is given for more than ten days. The indications for parenteral administration are the same as in other serious diseases.

(5) *Smallpox*.—The sulphonamides exert no influence on the virus and therefore do not modify the toxic phase of the disease, but the pustular phase does appear to be modified, the lesions being arrested at the vesico-pustular stage with a resulting diminution or suppression of the secondary fever. The septic complications which occur so frequently in the focal phase are profoundly influenced; either they are prevented or rendered mild. Sulphanilamide is given four hourly and discontinued as soon as scab formation commences. Perhaps sulphathiazole or sulphadiazine would be better as the septic infection may be due to organisms other than streptococci.

(6) *Vincent's angina*.—Manson and Craig (1945) got good results by giving a 0.5 gm. tablet to dissolve on the tongue every two hours during the day and 2 tablets every four hours during the night. Temperature usually returned to normal in 24 hours with almost complete disappearance of symptoms. Treatment was continued for 72 hours except in mild cases in which it was terminated at the end of 48 hours. Lesions invariably cleared in 96 hours after beginning of treatment.

Prophylactic use

In certain instances the sulphonamides are of value in prophylaxis, but they should not be indiscriminately used, and in no case for more than a week or ten days. Comparatively small doses are given. Sulphadiazine and sulphamerazine may be employed with advantage as they remain longer in the blood owing to slow excretion.

In patients requiring *tonsillectomy* or *extraction of teeth*, in whom the presence of a streptococcal infection is suspected, the drug is given

two hours before the operation and continued in 1 gm. doses at four-hourly intervals as soon as possible after the operation for two days. For *post-partum* cases in which there has been considerable interference similar treatment should be given but continued in reduced doses for a week. To prevent *urinary tract infection*, e.g. after instrumentation or when an indwelling catheter is required for some days, sulphanilamide or sulphadiazine is given at first four hourly and then six hourly. Sulphonamides have no action on *measles*, but given for a week after the appearance of rash, greatly diminish the occurrence of otitis media and bronchopneumonia. Similarly in *diphtheria*, after tracheotomy, the use of these drugs has almost eliminated broncho-pneumonia. In outbreaks of *cerebro-spinal fever*, there is invariably a high incidence of symptomless carriers and this is efficiently lowered by giving sulphadiazine in 2 to 3 gm. daily doses for three days. To be effective, such prophylactic courses should be applied to a closed or semi-closed community as in school, ship or camp and they are useless in an open population where chances of re-infection is considerable. In outbreaks of *bacillary dysentery* as in residential schools, symptomless carriers are also common and spread the disease. To control the infection, 1 to 2 gm. daily doses of sulphaguanidine are given until a few days after clinical cases have ceased to occur. Succinyl sulphathiazole is more effective when the infection is due to *Sonne bacillus*. Experiments under war conditions have proved that sulphathiazole or sulphadiazine has considerable value in the prevention of *gonorrhoea* and *chaneroid*. According to one method 2 gm. of sulphathiazole are taken either one hour before or within three hours of exposure; in another, three doses of this drug (3 gm., 2 gm. and 1 gm. at intervals of four hours) are taken during the 12 hours after exposure. Lees (Dunlop *et al.*, 1946) recommends an ointment (calomel 33.3 per cent, sulphathiazole 10 per cent and hydrarg oxycyanide 0.1 per cent in a base of equal parts of adeps lanae hydrosus and soft paraffin) as an additional protection. It is conveniently dispensed in collapsible tube. About 2 gm. of the ointment are rubbed into the genital area, particularly the coronal sulcus and frenum, and a small quantity is introduced into the meatus.

LIXEN
BRAND

*The
Good-natured
Laxative*

Lixen is an extract of senna prepared by a special cold process to allay the griping action. The absence of an after-constipating effect gives it a special value in habitual constipation, and its gentle, though efficient, action, together with its pleasant flavour, makes it particularly acceptable to women, children, elderly and delicate persons, and convalescents, for whom the finding of a satisfactory aperient is often difficult.

LIXEN Elixir

In bottles of 4 oz., 8 oz., and 16 oz.

LIXEN Laxative Lozenges

In tins of 12, and 24, and bottles of 100

PROTEIN DIGESTION RESTORED BY BOVRIL

Conclusive result of medical experiments

In many illnesses, when gastric secretion is impaired and is deficient in hydrochloric acid, Bovril corrects this condition by restoring the normal volume and activity of the gastric juice, thus aiding the peptic digestion and absorption of protein foods.

In 1911, the late Professor Thompson, of Dublin, established that Bovril had the power of ministering to nutrition by the assistance it gave to the assimilation of other foods. Recently a remarkable series of experiments has been conducted at an English University. A group of medical students volunteered to undergo the unpleasant experience of allowing the passage of an oesophageal tube into the stomach so that accurate studies might be made of the effect of certain beef preparations. One of the substances investigated was Bovril.

As a result of these experiments (described in detail in the *British Medical Journal* of August 28th 1937) Bovril emerged as 'the most effective stimulant.' Briefly, it was proved that Bovril increased the supply of gastric juices where there was a deficiency and restored it to normal. It is an accepted medical fact that people of sedentary habits generally suffer from a lowering of the essential gastric activity; Bovril rectifies this and, by facilitating the digestion of proteins, enables full nourishment to be gained.

Everyone, therefore, who is run down through strain or illness, or who feels in need of extra strength to cope with the demands of modern life, should take a cup of hot Bovril daily. It is a delicious and stimulating way of keeping fit and strong.

ANAHÆMIN B.D.H.

For the treatment of
Pernicious and other Macrocytic Anæmias

Clinical experience over a decade has established the remarkable hæmopoietic activity of Anahæmin B.D.H. in pernicious and other macrocytic anæmias. The potency of Anahæmin B.D.H. is such that it is effective in small doses at comparatively infrequent intervals both in the initial treatment of pernicious anæmia patients and in their subsequent maintenance.

Further, adequate (but still economical) dosage of Anahæmin B.D.H. is efficient in preventing the appearance and in arresting the progress of subacute combined degeneration of the cord and in eliminating those of the signs and symptoms which are remediable.

Stocks of Anahæmin B.D.H. are held by leading chemists and full particulars are obtainable from—

WATSON 'MX-2' X-RAY APPARATUS

The portable with the big performance

Compact and easily dismantled, Type MX-2 has the power for a wide range of radiographic procedures.

The rating is 80 kVp. at 15 mA; it has a generous screening rating, mains compensator, kilovoltage and mA controls and a 12 second timeswitch.

Type "MX-2" was adopted as the standard portable by the Army Medical Services and is particularly well suited to strenuous use in remote regions, the shockproof tube head being sturdy and immune to atmospheric conditions.

Delivery can at present be made from stock; write for literature to Watson & Sons, manufacturers of the officially adopted apparatus for Mass Miniature Radiography.

MEDICAL MEN IN INDIA : TOO FEW OR TOO MANY

SUCH are the considered opinions of committees and officials after reviewing the situation from the point of view of health and new appointments.

Those who hold that India lacks medical men.—They quote European and American figures. In India there is 1 medical man to 6,000 people while in England there is 1 medical man to 1,000 people and in America 1 medical man to 750 people. Apparently nothing contradictory could be advanced against such a powerful array of figures. The good intentions of Bhore's report are based on the evidence of such figures (Bhore, 1946).

Those who hold that India has a surplus of medical men.—They are : (1) Administrative medical men who have to turn down sometimes dozens of medical men for a single, small and temporary appointment. (2) Teachers in post-graduate institutions who supply the eager recipients with extra doses of knowledge for additional letters of qualifications after their names. The ordinary qualification has been weighed by their pupils and found wanting. Such is the competition in an overcrowded profession. (3) Ordinary citizens in large towns like Calcutta who see so many young men past the student age and middle-aged men with stethoscopes round their necks, overcrowding buses and tramcars, at all hours of the day. (4) Those who ran military hospitals during the first half of the last war. As soon as the pay improved difficulties in the military medical service began to disappear remarkably rapidly, at least numerically. This enormous number of medical men left behind in civil practice, in towns, colleagues whose financial condition improved obviously. (Alas ! it is sliding back already. The accumulated wealth has been spent on births, marriages and deaths mostly and has failed to raise the standard of living permanently.)

Towns are overcrowded by medical men.—Such is the real state of affairs. The overcrowding is lowering the standard of living of and consequently interfering with the acquisition of professional efficiency by the majority of medical men in practice in towns. The town population is naturally losing faith in such medical men. The patients would rather go to some one 'in service' who can hardly attend to

them. The Western system of medicine is blamed. The half-starved private practitioner tightens his belt and further reduces his standard of living and efficiency : the vicious cycle is complete and gathers speed year by year.

The countryside has very few medical men.—In rural areas private medical practitioners are rare. Even government dispensaries are very few and they do not work to their full capacity. The staff idles half the time. If more dispensaries were opened the idleness would be increased proportionately. The reasons for this state of affairs, which can only be seen by the sons of the country who have worked in and out of the country, are : (1) The system of Western medicine, without modifications, does not suit the rural masses. Symptomatology which is subjective and based entirely on the outlook, imagination and psychology of the simple folk brought up on simple centuries old lore is the chief difficulty. The physician has not read of 'circles', 'tightness of the heart' and 'twists of the rope', while the patient has not heard of 'biliousness', 'heartburn' and 'nerves'. Even leading questions fail. The paralysis of anti-rabies treatment was not recognized in India for a long time, mostly because the complaint-cards received could not be interpreted (Greval, 1936). Another difficulty is the palate. Flavours (flavour of bitter almonds, for instance) and tastes (taste of bitters, for instance) regarded pleasant by most Europeans nauseate most Indians. The sight also plays a part. Small quantities of mixtures (implying concentration of 'sharp' and 'hot' drugs) tinged with colours not encountered in daily food and drink do not appeal. Decoctions, infusions, confections, syrups, powders and pills, of suitable colour, flavour and taste will be more acceptable. The last though not the least difficulty is the cost of the treatment. Drugs manufactured in Europe and America by highly paid labour cannot be purchased by a population subsisting on the lowest possible income. The dispensing needs careful control if the effective dose of an expensive drug is to be given free. (2) The fee charged by medical men is exorbitant compared to the fee charged by an ordinary English practitioner in England and an equally ordinary *hakim* in India. The former charges (pre-World War II scale) one shilling in his surgery. The shilling consists of 12 buying units in England. In India 12 buying units are 12 pice (pre-World War II scale) which equals 3 annas. Any charge over 4 annas is excessive. The minimal fee accepted in India is Re. 1 to which the ordinary medical man is not entitled in equity and which is exorbitant. Of 4 annas he will probably collect 10 to 20 in a day in a rural population, in addition to what he receives in kind which every medical man receives in English country practice. Besides, he will live in his own house and grow his own food. (Every man owns a house somewhere or other in India.) The crowning glory of his career, when he succeeds, will

be the fact that he would be a 'social physician protecting the people and guarding them to a healthier and happier life' of Bhowe's report. He will then succeed where administrators have failed since Akbar's time if not Asoka's. He will give a new outlook to the masses. He may come to a town when he can afford it, if he has the urge. (3) Paid posts are the objective of the would-be medical men, not an interest in the medical profession itself. That is why the cry for an M.B. is so loud by those possessing an L.M.S. or L.M.P. What is wrong with L.M.S. or L.M.P.? There are three qualifications in England also. Once the knowledge has been acquired it can be perfected only in practice. Would it not be a good idea for many to acquire the knowledge quickly? They could even do so in their own mother tongue. There is an advantage in separating the essential from the non-essential under certain circumstances. Higher qualifications of some type or other and diplomas in specialities can be made available to all as they are in England. The rest will lie with the man. He is to be essentially a man with a profession, not a job hunter.

The method of admission of students may go far towards restoring the balance.—While in countries without caste the medical profession is becoming a caste, in caste controlled India the profession of medicine is not being handed over from father to son, as it should be. The responsibility lies with the authorities controlling medical education. Places in examination in pre-medical education are not a sound criterion of the suitability of the candidate. The admission should be by the place in the examination plus an interview and the interview should be important. Such is the contemporary English opinion also (Smyth, 1946; Editorial, *B.M.J.*, 1946). A medical man's sons and daughters should not fail to get in. They have grown up in a medical atmosphere and are not only in possession of its etiquette and tradition as applied to Indian soil but also have business interests and connections. For them there will be a place to make themselves useful anywhere, town or country. They and only they can change the outlook of the masses who under the influence of a strange blend of fatalism, ignorance and arrogance, born of centuries old frustrations and hardships of life, do not want medical men trained in the Western system of medicine. This outlook together with the fact that the system has not been modified to suit the masses makes the majority of medical men in India unwanted.

Old Tales Retold With Fresh Comments

OATH OF HIPPOCRATES

From *Encyclopædia Britannica*, 1938, 14th Edition, Vol. 15, p. 198

I WILL look upon him who shall have taught me this Art even as one of my parents. I will share my substance with him, and I will supply his necessities, if he be in need. I will regard his offspring even as my own brethren, and I will teach them this Art, if they would learn it, without fee or covenant. I will impart this Art by precept, by lecture and by every mode of teaching, not only to my own sons but to the sons of him who has taught me, and to disciples bound by covenant and oath, according to the Law of Medicine.

The regimen I adopt shall be for the benefit of my patients according to my ability and judgment, and not for their hurt or for any wrong. I will give no deadly drug to any, though it be asked of me, nor will I counsel such, and especially I will not aid a woman to procure abortion. Whatsoever house I enter, there will I go for the benefit of the sick, refraining from all wrong-doing or corruption, and specially from any act of seduction, of male or female, of bond or free. Whatsoever things I see or hear concerning the life of men, in my attendance on the sick or even apart therefrom, which ought not to be noised abroad, I will keep silence thereon, counting such things to be as sacred secrets.

From *Medical Journal of Australia*, Vol. I, 22nd June, 1946, p. 877—Francis Adam's translation

I SWEAR by Apollo the physician, and Æsculapius, and Health, and All-heal, and all the gods and goddesses, that, according to my ability and judgment, I will keep this Oath and this stipulation—to reckon him who taught me this Art equally dear to me as my parents, to share my substance with him, and relieve his necessities if required; to look upon his offspring in the same footing as my own brothers, and to teach them this Art, if they shall wish to learn it, without fee or stipulation; and that by precept, lecture, and every other mode of instruction, I will impart a knowledge of the Art to my own sons, and those of my teachers, and to disciples bound by a stipulation and oath according to the law of medicine, but to none others. I will follow that system of regimen which, according to my ability and judgment, I consider for the benefit of my patients, and abstain from whatever is deleterious and mischievous. I will give no deadly medicine to anyone if asked, nor suggest any such counsel; and in like manner I will not give to a woman a pessary to produce abortion. With purity and with holiness I will pass my life and practice my Art. I will not cut persons labouring under the stone, but will leave this to be done by men

who are practitioners of this work. Into whatever houses I enter, I will go into them for the benefit of the sick, and will abstain from every voluntary act of mischief and corruption; and, further, from the seduction of females or males, of freemen and slaves. Whatever, in connection with my professional practice or not in connection with it, I see or hear, in the life of men, which ought not be spoken of abroad, I will not divulge, as reckoning that all such should be kept secret. While I continue to keep this Oath unviolated, may it be granted to me to enjoy life and the practice of the Art, respected by all men, in all times! But should I trespass and violate this Oath, may the reverse be my lot!

Observations are necessary on three points: (1) Lack of co-operation between medicine and surgery—such as it was in those days. (2) Lack of co-operation between colleagues. (3) Prevalence of a social conduct of which other nations did not approve and which must be called a failing. In this connection the following account from *Lyon's Medical Jurisprudence*, 10th edition (in the press) will be of interest:—

Homosexuality amongst males was a well-recognized practice in ancient Greece.

'Personal affection was not the basis of married life; romance took a different form, that of passionate friendships between men. Such friendships among the Greeks were an institution. Their ideal was the development and education of the younger by the older man, and they were recognized and approved by custom and law as an important factor in the state. In Sparta, for example, it was the rule that every boy had attached to him some elder youth by whom he was constantly attended, admonished and trained. The celebrated "Theban band", consisting exclusively of pairs of lovers, marched and fought in battle side by side, and by their presence and example inspired one another to a courage so constant and high that "it is stated that they were never beaten until the battle of Chaeronea, and when Philip, after the fight, came to the place where the three hundred lay dead together, he wondered, and understanding that it was the band of lovers, he shed tears" (Plutarch, Pelopidas, ch. 18). Greek legend and history resound with the praises of friends, names that recall at once all that is most romantic in the passion of Greece. Not only, nor primarily, the physical sense was touched, but mainly and in chief the imagination and intellect. The affection of Achilles for Patroclus is as intense as that of a lover for his mistress (Iliad, XXIV). It was his insistence on friendship as an incentive to a noble life that was the secret of the power of Socrates. So much, indeed, were the Greeks impressed with the manliness of this passion, with its power to prompt to high thought and heroic action, that some of the best of them set the love of

man for man above that of man for woman. It is in the works of Plato that this view is most completely and exquisitely set forth; among all the forms of love, that one is chief which is conceived by one man for another. Such a love is the initiation into the higher life, the spring at once of virtue, of philosophy, and of religion. That there was another side to the matter goes without saying. This passion, like any other, has its depths as well as its heights. Still the fact remains that it was friendship of this kind that supplied to the Greeks that element of romance which plays so large a part in modern life: and it is to this, and not to the relations between men and women, that we must look for the highest reaches of their emotional experience' (Stanley-Jones, D., *Medical Press and Circular*, June 12th, 1946; an abstract from *The Greek View of Life* by Dickinson, G. L., 19th edition).

While the Greeks made no problem of this difficult question their Hebrew neighbours across the Mediterranean thought otherwise. In the mist of antiquity '... the Lord rained upon Sodom and upon Gomorrah brimstone and fire' (Genesis 19, 24), because their sin was 'very grievous' (Genesis 18, 20).

Very early in the Christian era St. Paul deplors the prevalence of the sin amongst the Romans who '.... leaving the natural use of the woman, burned in their lust one towards another; men with men working that which is unseemly,' (The Epistle of Paul the Apostle to the Romans, 1, 27).

Medical News

THE PLACE OF CANCER IN THE MEDICAL SCHOOL CURRICULUM

TWENTY-FOUR physicians representing 14 medical schools are meeting on 7th November with the National Advisory Cancer Council to plan an attack on cancer from the angle of medical education.

In announcing the meeting, which is being held at the National Cancer Institute in Bethesda, Maryland, Dr. Thomas Parran, Surgeon-General of the U.S. Public Health Service, said that these men are members of a special committee appointed to advise the Council concerning the place of cancer in the medical school curriculum. The disease now ranks second as a cause of death in this country.

The appointment of this committee is a step forward in putting into operation one phase of the accelerated cancer-control programme outlined last spring by the Committee on Cancer Facilities and Services of the National Advisory Cancer Council. The proposed programme would include more comprehensive and better integrated courses in cancer at medical schools.

Dr. Frank E. Adair, member of the National Advisory Cancer Council, heads the new committee. Dr. Adair is president of the American Cancer Society and Professor of Surgery, Cornell University Medical College.

Members of the Committee include:—

Chicago, Illinois

Dr. Roland W. Harrison, Dean, Division of Biological Sciences, University of Chicago.

- Dr. Charles B. Huggins, Professor of Surgery, University of Chicago Medical School.
 Dr. A. C. Ivy, Acting Dean, University of Illinois College of Medicine.
 Dr. J. R. Miller, Dean, Northwestern University School of Medicine.
New Orleans, Louisiana
 Dr. M. E. Lapham, Dean, Tulane University School of Medicine.
 Dr. Edward W. A. Ochsner, Professor of Surgery, Tulane University School of Medicine.
New York, New York
 Dr. Joseph C. Hinsey, Dean, Cornell University Medical College.
 Dr. Willard Cole Reppleye, Dean, College of Physicians and Surgeons, Columbia University.
 Dr. Currier McEwen, Dean, New York University College of Medicine.
 Dr. John H. Mulholland, Professor of Surgery, New York University College of Medicine.
 Dr. George H. Humphreys II, Professor of Surgery, College of Physicians and Surgeons, Columbia University.
Boston, Massachusetts
 Dr. Grantley W. Taylor, Professor of Surgery, Harvard University Medical School.
Minneapolis, Minnesota
 Dr. Harold S. Diehl, Dean, Medical School, University of Minnesota, Minneapolis.
 Dr. Owen H. Wangenstein, Professor of Surgery, Medical School, University of Minnesota, Minneapolis.
Madison, Wisconsin
 Dr. Wm. D. Stovall, Professor of Hygiene, University of Wisconsin.
 Dr. Erwin R. Schmidt, Professor of Surgery, School of Medicine, University of Wisconsin.
New Haven, Connecticut
 Dr. Milton C. Winternitz, Professor of Pathology, Yale University School of Medicine.
 Dr. George M. Smith, Executive Director, National Advisory Cancer Council. Address: Yale University School of Medicine.
San Francisco, California
 Dr. Francis S. Smyth, Dean, University of California Medical School, San Francisco.
 Dr. H. Glenn Bell, Assoc. Professor of Surgery, University of California Medical School.
 Dr. Emile Holman, Professor of Surgery, Stanford University School of Medicine.
Emory University, Georgia
 Dr. Daniel C. Elkin, Professor of Surgery, Medical School, Emory University.
Washington, D. C.
 Dr. Lewis H. Weed, Chairman, Division of Medical Sciences, National Research Council.

CALCUTTA SCHOOL OF TROPICAL MEDICINE. TWELFTH CLINICAL MEETING HELD ON 4TH DECEMBER, 1946

Dr. GODREJ S. KARAI demonstrated a case of carcinoma rectum in a Hindu male aged 52 years. A perineo-abdominal procto-sigmoidectomy had been performed in this case by Major A. T. Andreasen two months ago. The case was admitted in an emaciated condition weighing only 5 stones 11 pounds, complaining of increasing constipation for 5 months and pain in the rectum particularly during defaecation for 3 months. Pain was local, with reference occasionally to the gluteal and sacral regions; hæmorrhage was an infrequent symptom during defaecation. He had been treated medicinally for hæmorrhoids.

Rectal examination showed the presence of a firm, annular tumour mass around the walls of the rectum, about 2½ inches from the anal margin. Its upper border could not be reached; its lower border presented a rolled up ragged edge, firm and nodular in parts. Red cell count 4.3 millions, hæmoglobin 80 per cent (Sahli); white cells 6,300, polymorphs 65 per cent; total plasma

proteins 4.14 per cent, albumin-globulin ratio 1.86/2.28. Two stool examinations showed red cells in fair numbers, no amœbæ. Inguinal lymph glands were not enlarged and liver and spleen not palpable.

On a diagnosis of carcinoma rectum (ampulla) a left inguinal colostomy was opened two days after admission. Light spinal percaïne 16 c.c. and intravenous drip sodium pentothal (induced with 5 per cent solution and maintained with 2 per cent) were given for anaesthesia. The lower end of the left ureter was scarified during operation because of extension of the growth around it. The pathological specimen prepared by Dr. R. N. Chaudhuri showed a large ulcerating growth of the rectum about 2½ inches from the anal margin and 4 × 2 inches in size. The floor was deeply ulcerated and bleeding, margins rolled up and surrounding area indurated. It was graded as class C (Cuthbert Duke), i.e. involvement of the muscular and peri-rectal fascia, but no involvement extensively in the local lymph glands.

Radium implantation via a rubber tube anchored in the lumen of the rectum was unsuccessful. Dressing twice a day of the colostomy opening, wash-outs of the excluded lower bowel segment and rectum with tepid normal saline and instillation of 4 oz. olive oil via the colostomy were the important points in the maintenance and care of the colostomy (primary). A low residue, high protein diet was supplied and two full courses of sulphasuxidine were administered.

Major Andreasen pointed out that the fears of the profession regarding the mortality from such operations were out of proportion to the facts. In the best hands class C and D cases (Cuthbert Duke) had an immediate operative mortality of 12-15 per cent, while class A tumours had a recovery and absence of recurrence in a 5-year period of over 80 per cent. He stressed the importance of early recognition and treatment in all such cases. The abdominal wound usually closes well in spite of the adjacent colostomy, and the perineal aspect takes approximately 80 days for the cavity to granulate up to the surface if dressed by the occlusive technique.

In replying to Dr. Panja's query as to the differentiation of these tumours from amœbomas, he stressed the more important need of recognizing the carcinoma and giving the patient the benefit of early radical surgery. Suspicious cases should be given the advantage of frequent stool examinations, biopsy and sigmoidoscopic examination besides thorough clinical examination. The finding of a tumour with *E. histolytica* in the stool is no criterion for a diagnosis of amœboma; the dangerous malignant growth must be proved absent before such a diagnosis can be entertained.

Dr. C. R. Das Gupta described a case of Cooley's anaemia. The patient was a Hindu female child in Bengal of Bengali parents. The child was reported to have been suffering from intermittent fever off and on, and progressive anaemia not responding to treatment for over one year. Clinically, the patient looked very pale with characteristic mongoloid facies with a big head and had a protuberant abdomen. The spleen was greatly enlarged about 6 inches and was firm. The liver was also enlarged about 2 inches. Systolic bruit could be heard over the mitral and pulmonary areas of the heart. There were scattered rhonchi over both the lungs. Examination of the blood showed hypochromic anaemia of moderate degree. The blood smear showed numerous immature cells, mostly normoblasts and a few neutrophil myelocytes, but careful examination failed to show any 'target cells'. The red cells did not show any increased resistance to hypotonic saline. Sternal marrow was cellular with preponderance of normoblasts. Radiologically the skull bones presented vertical striations characteristic of Cooley's anaemia. Treatment with iron for over 30 days showed only slight improvement in the blood counts and the blood picture continued to be hypochromic. The number of immature cells in the peripheral blood did not show any diminution.

Dr. N. V. Bhaduri described a case of dracontiasis in a Punjabi Mohammedan male aged 40. The patient visited his native place, an endemic area, about a year and a half ago. Towards the end of October 1946 one night he had an attack of urticaria in the right leg followed by loose stools. The next morning his symptoms disappeared but a blister appeared in the lower part of his right leg. Two days later a guinea-worm appeared through the blister; later on another ulcer appeared on the dorsum of the same foot through which three more worms came out after which there was complete abatement of symptoms. X-ray examination of the leg showed the presence of a calcified worm.

Dr. R. N. Chaudhuri gave an account of treatment of malaria with paludrine in a series of 43 cases. The following regimes of treatment were tried: I. One tablet (100 mg.) three times a day for four days. II. A single dose of 3 tablets. III. A single dose of one tablet. Charts showing the effects of the drug on the temperature and parasites were demonstrated. These indicated that the average effect of treatment with all the regimes considered together was to bring (1) the temperature to normal in 53 per cent of the cases in 3 days and in 95 per cent cases in 4 days, and (2) to cause disappearance of parasites in 67 per cent in 3 days and in 93 per cent in 4 days. Gametocytes, especially the crescents, remained unaffected. In two cases of falciparum malaria schizonts were seen in the peripheral blood after paludrine administration. As regards relapses, quarter of the cases of single dose treatment relapsed within three weeks while none of those treated with 12 tablets relapsed during this period of observation in the hospital. Two patients treated with single doses were subsequently given one tablet weekly for six weeks and they had remained well so far. No untoward symptom or evidence of idiosyncrasy was encountered. One patient, a woman, was six months' pregnant with severe anaemia and had paludrine treatment without any side effects.

FUNCTIONAL DESIGN OF AUSTRALIAN HOSPITALS

(Australian Medical Newsletter No. MNL/III)

FUNCTIONAL design in Australian architecture is best exemplified in the country's hospitals, which are claimed to be equal to the finest in the world. This article deals with three in the State of New South Wales.

Sydney architect and town planner Walter Bunning said recently: 'Hospitals are probably the only branch of our architecture about which such a claim could be made. The reason undoubtedly is that more research is made in the hospital field than in any other, and that it is the only field in which scientific planning dominates the desire to be romantic, and to imitate the glories of the past.'

'Even that most functional of all structures, the factory, is generally cloaked by a massive, pretentious facade on the main street, as though ashamed of its function. Cinemas and places of amusement are dressed up in cheap vulgar fancy dress. However, the hospital is looked upon rather as a laboratory, where one is made well, and the result is a clean, efficient-looking building.'

Mr. Bunning gives as an example of such a building the Rachel Forster Hospital, which was built to the design of Sydney architects Leighton Irwin and Co., and opened in 1942 in the Sydney suburb of Redfern.

This hospital is an excellent example of scientific planning. The vertical slab-like ward block is kept to one edge of the site, leaving freedom for air to circulate around the block, besides creating a sense of space. The outside appearance is cheerful, light and airy. The hospital's clean-cut lines impart an air of hygiene, and the white edges to the balconies and windows create much the same effect as white collars and cuffs to nurses' uniforms.

The noted French painter, Ozenfant, once said 'buildings need white collars'.

The outside treatment of the building depends for its effect of dignity and formality on the relation

between the long horizontal balcony lines of the ward-block and the slender vertical columns of the administration block, which is at right angles to it.

The balconies of the ward-block end in a concrete slab, brilliant white on the edge, matching the edges of the balconies themselves, which are grey-blue on the underside. The end wall of the ward-block is soft red brickwork, relieved by a surface sub-division into large square panels by recessing lines of brickwork.

Kitchen arrangements have been so designed that the food is received at the goods entrance, prepared and served, without once recrossing its tracks. Food lifts take it to the ward pantries.

Inside the hospital cheerful colours contrast with soft greys.

George V Memorial

Another hospital of which Sydney is proud is the King George V Memorial Hospital for Mothers and Babies, at Camperdown.

Designed by architects Stephenson and Turner, this hospital cost £(A)310,000 (Rs. 33,19,480) to build and £(A)45,000 (Rs. 4,86,860) to equip. The foundation stone was laid in 1939, and the official opening ceremony was performed in May 1941.

The hospital has long sun balconies running the length of the front facade. Built in cream bricks, it is decorated on either side of the facade with blue and cream panels of conventionalized designs of a mother and child. A strikingly modern entrance porch is supported by rich blue pillars of porcelain enamel.

The building is divided into obstetric and gynaecological sections horizontally and vertically. The third floor contains all operating and sterilizing services and investigation and examination clinics. Above this floor are the private wards, below it the public wards.

Colour schemes that alternate through the floors are blue and cream, grey-green and cream and rust and cream.

Among modern features are silent electric light switches in every ward, air-conditioned basinettes for the babies, dumb-waiters (trays on wheels) to bring meals straight up from the kitchens to the wards, and an operating theatre with domed ceiling of reflecting steel for indirect lighting on to the operating table, and with observation slits to allow students to watch through the ceiling.

All beds are nickelled to save repainting, and in most wards all the drawers in the furniture are swung out on swivels. Picture rails are an inset line in the wall. No sharp corners are allowed anywhere, even the sides of doorways being rounded.

New Military Design

At Concord West, Sydney, is the 113th Australian General Hospital, which presages a new era in military hospital design.

Gone is the customary severe and barrack-like building for the treatment and convalescence of soldiers. In its place is a hospital featuring the most advanced designs and equipment.

Stephenson and Turner also designed this hospital. The main way in which it differs from past military hospitals is that all the accommodation is grouped in large multi-storied buildings instead of being dispersed into numerous one-storied pavilions. These awkward structures used to be spread all over the site, linked by rambling corridors.

The Concord Hospital, completed in 1942 after only two years' building, has compact high blocks with vertical communication by high-speed lifts instead of slow horizontal foot traffic. The site is spacious, and instead of a lot of untidy huts there are broad sweeps of lawn, gardens and trees.

The main 7 storey ward-block is planned on an aeroplane-like shape. Subsidiary buildings have been grouped to increase the effect of mass and assertion. Wards open on to sunny balconies partly protected by glazed screens against the wind. From the outside these screens of glass, rising storey on storey, resemble a great laboratory.

SPECIALIST TRAINING FOR DOCTORS

By L. E. SESSEL

(Reprinted from the leaflet dated 20th January, 1947, published by the United Kingdom Publicity Services, New Delhi)

Doctors in Britain are to be enabled to enlarge their professional knowledge and improve their skill on more systematic lines than hitherto. Both specialists and general practitioners will benefit by the opportunities available.

With this object the British Postgraduate Medical Federation has been created in the capital as a 'school' of the University of London. Its purpose is to provide in London organized and correlated facilities for postgraduate teaching and research for qualified medical practitioners of the United Kingdom and from overseas countries, and to co-operate with other universities and medical schools similarly engaged.

Sir Francis R. Fraser, a distinguished physician, is the first Director of the Federation, which at once becomes the foremost institution of its kind in the United Kingdom. In a recent paper he read at Edinburgh, which bears a high reputation everywhere as a centre of medical training, he discussed the suitability of London not only as a centre of education for British doctors but as an international school to which numbers of foreign medicos would desire to proceed.

Postgraduate Education

Postgraduate medical education has, of course, existed as long as the profession of medicine, but it has engaged serious attention in Britain in organized form only since the beginning of the century. Obviously it is essential for specialists, and it is hardly less desirable for the general practitioner though the public's daily calls on his services, either as private or 'panel' (i.e. medical insurance) patients, often make it more difficult for him to find time for postgraduate study.

London has had its British Postgraduate Medical School at Hammersmith in the suburbs since 1935. It has done very useful work, canalizing effort in the capital and the Home Counties. Facilities there and on a smaller scale elsewhere are now to be extended under the direction of the new Postgraduate Medical Federation. Preferential consideration will generally be given to British ex-Service doctors in the first instance who are bent on additional medical education; but, with the satisfaction of these requests, the door will be freely open to doctors from other countries, many of whom are anxious to put in a course of study in London at the present time.

Comprehensive Field

The Federation will provide (i) training for prospective specialists, supplementing the work of the undergraduate medical schools, (ii) advanced revision for practising specialists, (iii) instruction for medical practitioners who, though not specialists, desire more detailed knowledge of any branch of medicine, and (iv) instruction for general practitioners. A pretty comprehensive field of activities is thus embraced.

It will include the departments of general medicine, general surgery, obstetrics and gynaecology, and pathology of the existing Hammersmith Postgraduate School, also the institutes associated with several London hospitals which specialize in the treatment of sick children, diseases of the nervous system, and throat, nose, ear and eye troubles. It is hoped to include an institute of psychiatry in the immediate future.

Expansion Programme

Associated with the Federation in providing postgraduate education are the teaching schools of many other important hospitals, which concentrate on the treatment of diseases of the skin, of tuberculosis and the chest, heart, genito-urinary and orthopaedic troubles. These schools are being expanded and developed as circumstances permit in order to include them as federated institutes in due course.

All these establishments are in London, which is far better equipped for postgraduate medical education

than any other centre in Britain. It shelters 12 great voluntary hospitals associated at present with undergraduate medical schools, 30 other large voluntary hospitals and innumerable smaller ones, special hospitals in every branch of medicine, and the largest and most efficient local authority hospital system in the world. It presents an unrivalled field for observation and study.

In the opinion of the Director of the Federation the ideal arrangement in London would be a general hospital and postgraduate medical school with specialist hospitals grouped around it, constituting a postgraduate medical centre. There would be residential accommodation and other amenities, together with proper administrative offices. These desirable objects are, however, unattainable at present, especially in view of post-war building and other problems. But the idea has not been abandoned, and an influential committee is considering what parts of the proposed centre should be completed first in order that the requirements of visiting graduates expected from overseas to take up courses may be met.

Hospital Appointments

Reference has been made to the facilities that are to be extended in the first instance to ex-Service doctors. This arises from a government scheme of assistance. They are being given hospital appointments for a period of six months in which to refresh their knowledge of various branches of medicine, and these appointments are extended for further periods for doctors selected for training as specialists.

The hospitals have been asked by the Ministry of Health to create some wholetime appointments for those whose specialist training is completed, as distinct from the honorary appointments hitherto held by trained specialists who attend the hospitals and deal with new variabilities in disease that constantly attract expert attention. The wholetime appointments will be made in anticipation of the coming into force of the important National Health Service Act in April 1948.

PLASTIC SURGERY GROWS UP

By L. E. SESSEL

(Reprinted from leaflet No. F.372, dated the 10th February, 1947, issued by the United Kingdom Publicity Services, New Delhi)

'Plastic surgery has suddenly grown up.' That was said by Mr. Archibald H. McIndoe, Consulting Plastic Surgeon to the Royal Air Force and Surgeon-in-Charge of the Maxillo-Facial Unit at the celebrated East Grinstead Centre, when addressing the Professional Nurses and Midwives Conference in London in December 1946.

The great progress in this field of surgical work is very largely attributable to the experiences of the two World Wars. Little was known or had been heard of plastic surgery in 1914. There were no plastic surgeons then and no particular likelihood of there being any. To-day, the situation is quite different. The almost incredible achievements of pioneers in their treatment of severe facial and other bodily injuries, particularly those caused in war, have become far more widely appreciated, and steps to meet the need for specialists, accommodation and equipment are being taken.

Great advances have taken place in Britain. At Queen Victoria Hospital at East Grinstead, Sussex, some 30 miles from London, there is a special centre where ex-Servicemen, especially airmen of Allied Forces during the Second World War, have received treatment demanding the highest degree of skill. Many of these cases are still being treated.

£97,000 Extension

During the war the Canadian Government, in token of gratitude for the care bestowed on their nationals at East Grinstead, added a wing to the centre, and in July 1946, Queen Elizabeth formally opened another

addition there, provided and paid for by Americans at a cost of £97,000. Its equipment is unsurpassed in any country.

This development in the field of plastic surgery in the past 30 years was authoritatively surveyed in his London lecture by Mr. McIndoe. He showed how the sudden urgent demand for plastic surgeons arose in 1916 owing to the flood of facial injuries, the special by-product of static trench warfare. At that time armies of men lay in concealment at close quarters, taking pot shots at every head or face that dared to show itself. That explained how as many as a thousand facially injured men went in one home-bound convoy urgently demanding skilful treatment.

With so many cases of the kind crowding in, a special centre was established at Sidcup, Kent, on the southern outskirts of London. 'At that centre, by trial and error, the principles of facial restoration and eventually of plastic surgery were laid down', said Mr. McIndoe.

Outstanding Pioneers

Two great reputations were made there—those of Sir Harold Gillies, now Plastic Surgeon at St. Bartholomew's, the famous 800-year-old hospital in the City of London, and Professor T. P. Kilner. They are the two outstanding pioneers of plastic surgery in Britain and possibly in the world. Gillies was elected first President of the Association of Plastic Surgeons formed in November 1946, with the assistance of the Royal College of Surgeons, while Kilner is the first Professor of Plastic Surgery at the University of Oxford established under the Nuffield Trust—a clear indication of the importance now attached to this specialized branch.

Plastic surgery became rather friendless when Sidcup, which had been fathered by the Red Cross, closed down after the first World War, having fulfilled its wartime purpose. Not a single teaching hospital had or wanted a plastic surgeon attached to its staff and only one non-teaching hospital provided beds.

But Gillies and Kilner persisted in the face of every obstacle in the task of defining and creating the field of plastic surgery in relation to civilian life. Briefly, the field included: (1) all kinds of injuries and deformities to the face resulting from accident and disease; (2) injuries of soft tissues in all other parts of the body, especially where losses of skin involved skin grafting. Finally, there is the whole field of congenital defects, such as cleft lip and palate among many others.

First Teaching Hospital

St. Bartholomew's was the first teaching hospital to recognize the importance of the subject when it appointed a plastic surgeon to its staff in 1935. Two other leading London hospitals followed the lead as well as half-a-dozen non-teaching hospitals, and by the end of 1939, there were four or five fully trained plastic surgeons. Fortunately—for the second World War had started—there were another 12 to 15 partially trained. But facilities for the surgeon and for the nursing of the cases were usually inadequate.

East Grinstead is gratefully remembered by thousands of Servicemen of all nations for its invaluable services during World War II. Whereas in the 1914-18 war the patients were chiefly army men, those of 1939-45 largely belonged to the air forces, airmen who were often shockingly burnt when their machines were shot down. The attention and skill bestowed on their terrible injuries have made new men of many of them physically and, by abolishing their former self-consciousness about their appearance, mentally.

The demand for wartime services is naturally diminished, but plastic surgery has no less important a place to fill under peacetime conditions. It has been estimated that to run a satisfactory service throughout Britain approximately 15 units of 100 beds would be required. With regard to the nursing of these plastic surgery cases, Mr. McIndoe has suggested that nurses

should be able to qualify for a special certificate, such as they can now obtain for midwifery, fever, orthopaedic, tuberculosis and mental training.

COMMITTEE TO CONSIDER THE CLAIMS OF THE INDIGENOUS SYSTEMS OF MEDICINE

At the Health Ministers Conference held in December 1947 at New Delhi, it was resolved that adequate provision be made at the centre as well as in the provinces for training and research in the indigenous systems of medicine and for the application of scientific methods for the investigation of those systems. In pursuance of that resolution, the Government of India have appointed a committee of representatives of the Ayurvedic systems of medicine and a system of medicine to consider the question in all its aspects and recommend steps that should be taken to improve facilities for research and training in indigenous systems of medicine with a view generally to increase their usefulness to the public. The personnel of the committee are Sir Ram Nath Chopra, Chairman; Vaid—Dr. A. Lakshminpathi (Madras), Dr. Balkrishna Chintaman (Bombay), Dr. B. A. Pathak (Benares); Hakims—Hakim Habibur Rahman (Dacca), Hakim Mohammad Hazzan Qureshi (Lahore), Hakim Nasiruddin Ahmad Khan (Delhi); Doctors—Major M. H. Shah, I.M.S., Superintendent, Irwin Hospital, Delhi, and Dr. B. N. Ghosh, Professor of Pharmacology, Carmichael Medical College, Calcutta.

The committee has already convened its first meeting on the 22nd March, 1947, at the Council House, New Delhi. This meeting will be opened by the Hon'ble Member in charge of the Health Department, Mr. Gazanfar Ali Khan.

CENTRAL DRUGS LABORATORY (GOVERNMENT OF INDIA), CALCUTTA

With effect from 1st February, 1947, the Government of India have decided to convert the existing Biochemical Standardization Laboratory at the All-India Institute of Hygiene and Public Health, Calcutta, into the Central Drugs Laboratory and has authorized this laboratory to perform the functions of the Central Drugs Laboratory under Section 6(1) of the Drugs Act, 1940. It is proposed to enforce this Act from 1st April, 1947.

Under the Drugs Act, 1940, the functions of the Central Drugs Laboratory will be as follows:—

- (a) To analyse and test samples sent to the laboratory on the provisions of the Act and the Rules thereunder by Customs-Collectors and Courts of Law.
- (b) To grant certificates of registration for patent and proprietary medicines with undisclosed formulae, and
- (c) To carry out such other duties and functions as entrusted by the Central Government.

Dr. B. Mukerji, M.D., D.Sc., F.N.I., officiating Director of the Biochemical Standardization Laboratory since 1941, has been appointed Director of the Central Drugs Laboratory with effect from 1st February, 1947. After graduating in 1927 from the Calcutta University Dr. Mukerji joined the Calcutta School of Tropical Medicine in 1928 as assistant research worker to Sir R. N. Chopra. He has been associated with the drug control movement since 1930 when he served as assistant secretary to the Drugs Enquiry Committee. In 1933 he was awarded the Rockefeller Foundation scholarship and he studied modern methods of pharmacological and biochemical research in America and Great Britain. Dr. Mukerji is a member of the American Society for Pharmacology and Experimental Therapeutics, of the Swiss Medical and Biological Society and of the editorial committee of the Indian Pharmacopoeial List.

NOTE ON INDUSTRIAL CANTEENS
IN CENTRAL PROVINCES

By D. M. ROY

*Nutrition Officer and Additional Inspector of Factories,
Canteens, Central Provinces and Berar*

Introductory: Origin of canteens.—Canteens were originally purely a military concern, but they have been a feature of wartime Britain where the economical distribution of food supplies, the need to help workmen to stick to their jobs in heavily bombed areas and the opportunities which such canteens provide for introducing the alternative diets dictated by rationing have all influenced government in its policy of promoting the setting up of canteens. Most important was the need to give special classes of the population special allowances of food. This could only be done without upsetting the whole ration card system and supply supplements at canteens reserved for special categories of the population (heavy industrial labourers' school, etc.).

Need of a canteen.—It has long been realized that poor feeding is one of the chief causes of high mortality and morbidity and low efficiency in labour in this country. Proper feeding, proper housing, proper hygiene and proper attention to the habits and customs of the labourer: these are as important as questions relating to hours of work and rates of pay in securing a contented and efficient labour force, and of these proper feeding is certainly not the least important.

Under present-day conditions of employment it is necessary for a great number of workers to live at a distance from their work so that they cannot afford either the time or the money to return home for a mid-day meal. They carry food with them which is neither balanced nor hygienic or they must take their meals at a neighbouring restaurant or tea-stall which is more expensive, at the same time ill-balanced. An industrial canteen run by the employer on a non-profit basis will provide better food with less money under conditions that are not possible elsewhere. The chance of rest in a bright and cheerful environment with opportunities of meeting friends and talking is welcomed as a complete break and relaxation during the working day. Besides supplying a balanced and nutritious food to the worker it teaches the worker what is a scientific diet and what things are necessary from a nutritional point of view which will greatly influence his dietary at home and in his family.

Industrialists in Europe and America have developed canteens to a high degree of perfection: What have we achieved in this direction in India?

In Central Provinces and Berar there are 819 factories out of which a dozen have got

canteens serving tea and snacks. One of them serves in addition balanced meals. The tea canteens supply snacks as *nimki*, sweets, *chura*, and also cold drinks. The snacks have got very little nutritional value and the quantities consumed are so small that they do not supply even the required calories not to speak of vitamins and minerals. The availability of milk and butter-milk is good although the amounts consumed are small.

The only canteen where cooked balanced meals are served is in the All-India Reporters at Nagpur. The attempt of the management is commendable. Though they have not been able to construct an up-to-date canteen building with all the paraphernalias of a modern canteen they serve the balanced meal to the workers in a modest way. A full meal consisting of rice, chapatti, dhal, vegetables, chutney, onion, tomato, chips and *lassi* can be had for about 4 annas. Dhal, vegetable and chutney are given free to every customer of a balanced full meal. The canteen staff besides their pay are given free meals in the canteen. The management is trying a scheme of extending the facilities of balanced cooked meals to the families of the workers which if successful will be a new achievement of industrial canteens not only in Central Provinces but in India. Thirty-five workers have so far enlisted for taking facilities of the canteen to be extended to their families.

In Central Provinces there are two types of canteen managements, one set of canteens is managed by the employers and the others by contractors. The quality of the foodstuffs is better and the price is comparatively lower in canteens managed by the employers as in Empress mills, All-India Reporters, Pulgaon Cotton mills, Reek Chand Gopaldash Mohota mills, The Savatram Ramprasad mills and Vidarbha mills, than in mills run by contractors as in Model mills, Rekehand Mohota spinning and weaving mills. The contractors of course are ordinary commercial firms and have to make profit.

Prospects of extending cooked balanced meal canteens in factories.—While discussing with the managements the feasibility of introducing cooked balanced meals in factory canteens in preference to tea and snacks, certain difficulties, though not unsurmountable, were realized for introducing such cooked meals. The problems and their suggested solutions may be stated as follows:—

(a) *Cost.*—A balanced meal will naturally cost more than the poor *bhakri* (chapatti) and chutney that the workers get from their homes for the mid-day meal during the noon recess. The workers are not prepared or cannot afford the extra money for a better meal. They expect

and want it at the same cost if not less than what they spend on their traditional *bhakra*. This question of cost can be solved if the employers subsidize the cost to the extent of at least half. The alternative solution would be to raise the wages of the workers to a 'living wage' standard according to local conditions provided that every worker shall take a balanced meal in the canteen.

It is doubtful if these measures will be voluntarily adopted either by the employers or the employees unless the government make those measures obligatory through legislation.

(b) *Education of the employees and employers.*—It has to be brought home to the workers that a balanced diet is a necessity for health and happiness and ultimately for increasing their earning capacity to their own benefit. The employers have yet to understand that spending money to feed the workers is no bad investment, it will ultimately pay in return of increased output and more profit. Most workers have no money left, after feeding and clothing themselves and their families, to improve the diet. Prohibition may cause some reduction in spending on luxury but the labouring man must have some mental and physical relaxation. If he can't drink he will gamble or try illicit drink. Planned recreation facilities are as essential as canteens or nearly so.

(c) *Co-operation.*—There is a sense of distrust prevailing between the employers and the employees. Any new action undertaken by the employer for the benefit of the employees is looked upon with suspicion and thought to be meant for the benefit of the employers only. Unless the workers give their full co-operation and take advantage of the factory canteens they will always be running at a loss. Almost all the canteens which are run by the employers in Central Provinces have been running at a loss. In fact two factories introduced balanced meals in their canteens and had to discontinue them for want of sufficient support from the workers.

To win the confidence of the workers they must be represented by at least 50 per cent in the managing body of the canteen. And the running of the canteen on a co-operative basis will go a long way to get the largest response from the workers.

(d) *Religious susceptibilities.*—No worker would object to drinking tea and snacks with fellow workers of other religions or castes but the ghost of caste prejudice at once haunts him as soon as he has to take cooked meals with them.

At the start arrangements will have to be made in conformity with the religious susceptibilities, but they may lapse after a time.

The fact that he spent his cash on frivolous amusement, etc., is due to his lack of appreciation of the need for better food for himself and his family and his ingrained conservatism and contentment with a very low standard of living.

The uneducated definitely need education on this matter.

Absenteeism is mainly due to (i) fatigue and (ii) unusual cash receipts, a man used to very low wages feels rich and does not feel the need to work regularly.

Unless and until better housing is provided for the industrial worker I feel it will be impossible to make him appreciate the value of a better standard. This has been the experience in Europe both during the industrial revolution in the middle of the nineteenth century and in more recent years following slum clearance activity. Give a man the possibility of a decent home life and he will quickly develop personal pride and joy in his house and family and will make effort to improve his position still further.

Till such time as the workers do not attain that mental state of voluntary co-operation they will have to be persuaded by some sort of compulsion to spend a reasonable proportion of their 'living wages' for a balanced meal in the factory canteen.

My grateful thanks to Colonel L. K. Ledger, O.B.E., I.M.S., for his kind permission to publish this article.

RICE GRUEL IN FOOD PREPARATIONS

SCHOOL-FEEDING EXPERIMENTS WITH KANJI (GRUEL) PUDDING AT BANGALORE

By S. S. DE

H. S. R. DESIKACHAR

A. T. DUDANI

B. T. KARNANI

and

V. SUBRAHMANYAN

*Department of Biochemistry, Indian Institute of Science,
Bangalore*

DURING the cooking of rice in water a certain portion passes into solution and that is usually rejected because it interferes with the appearance, taste, flavour, keeping quality and digestibility of cooked rice. In some parts of the country, extra quantity of water is added and the liquid drained again to remove the last traces of the gruel. This practice is still being continued in spite of the increasing amount of knowledge regarding the attendant loss of vitamins, proteins, minerals and other essential food substances in the gruel.

*Rice Gruel is best separated and used with
other foods*

The general practice is not altogether faulty : in fact, it is now established that the rice with the gruel adhering to it becomes a pasty mass that is not easily penetrated by digestive juices. Rice is best digested when the cooked grains

remain separated and that would be possible only by removing the gruel. A practical approach to the problem would therefore be to separate the gruel from rice and use it as a food in some other form.

The gruel may contain 4 to 10 per cent solids, depending on the variety and condition of rice, degree of boiling, amount of water added and so forth. The gruel from previously washed raw rice is a fairly clean product containing 6 to 8 per cent starch: that from parboiled rice is usually thinner (containing 2 to 4 per cent starch) and somewhat strong in smell. The vitamin, protein and mineral contents are variable, depending on the extent of washing prior to cooking. If the washing is not extensive, the major part of the water soluble vitamins would pass into the gruel.

*The Gruel can be mixed with milk for
souring*

Rice gruel develops acidity on standing, lactic acid being the chief product. The fermentation proceeds quite smoothly on admixture with cow or buffalo milk. We have found that the gruel could be added to the extent of 25 to 30 per cent of the volume of milk and that the mixture develops acidity and sets to a thick curd as in the case of pure cow or buffalo milk. This would definitely be an advantage to homes which prepare their own curd and butter-milk and which could do with some extra supply. The acidity developed during the lactic fermentation helps to preserve the vitamins and this procedure would therefore be a simple and elegant method of using the gruel produced in most homes. The attendant chemical and biological changes have been studied and will form the subject of another communication.

Another and an equally elegant method would be to set the gruel to a solid and to use it as a sweet pudding. This type of preparation is quite popular besides being fairly cheap.

Preparation of Kanji (Gruel) pudding

At the invitation of the Bangalore Civil and Military Station authorities, we took up the standardization of conditions for this preparation and to produce it on a sufficiently big scale to provide mid-day meal for about 1,100 children per day. The procedure followed by us may be outlined as follows: The gruel (about 600 lb.) is obtained through the courtesy of the 6 M.T.T.C. and delivered each day between 12 noon and 2 p.m. It is not required till the next morning, so we bring it to a quick boil and store it in previously steamed vessels. On the day of use, it is again raised to boil and roasted, white wheat flour (35 lb.) in the form of a paste is added in rapid instalments with stirring. Sugar (35 lb.), salt (3 lb.) and edible colour (yellow, orange or any other pleasing shade) are added in quick succession. After about 15 minutes of cooking, a flavouring

material (cardamom powder or vanilla essence) is added and the pudding, which is already fairly thick, rapidly transferred to the storage vessels and allowed to set. It is then sent out to the schools for distribution to the children at half a pound per child.

It may be added that if previously boiled, the gruel keeps well for even 24 hours. Wheat flour roasted to a crisp brown (by heating in cast iron pans) cooks more easily, sets better and imparts a more agreeable flavour than the raw flour. Rice or corn starch can be used in place of wheat, but they are more expensive at the present time. Whole jowar or maize imparts a bitter taste besides feeling rather coarse on the tongue. With some processing, these millets can be used in place of wheat. Sugar is the most expensive item in the preparation, but we have found it difficult to reduce it to less than 7 per cent on the weight of the gruel. We have tried to replace sugar partly with saccharine, but the resulting preparation has not the same good taste or food value as that of the preparation with sugar. Gur (jaggery) affects the flavour: moreover, it is now more costly than white sugar. Cane juice can be used in place of white sugar, and where it is available, it will be advantageous to use it after neutralization and clarification. Increasing amounts of salt up to 0.5 per cent improve the taste. Edible colours are available and we have found that the yellow and orange impart pleasing shades. We were first using vanilla essence (made up with vanillin, coumarin, glycerine and alcohol) but found later that powdered cardamom (20 tolas to 500 lb. of gruel) imparts a more pleasing flavour.

The pudding thus prepared is best consumed within 8 to 10 hours after preparation. It can be kept longer in cold storage, but this facility may not be generally available. On prolonged standing the jelly breaks up, accompanied by development of acidity and other secondary changes which should be avoided.

*Incorporation of Soya paste improves taste
and flavour*

For some time we were incorporating 2 per cent skimmed milk powder but had to subsequently give it up because of the cost. More recently we have been incorporating the paste* obtained after pressing out soya milk at the rate of 125 lb. to 500 lb. of rice gruel. This addition improves the taste and flavour. Our total production now works out to about 675 lb. of pudding per day.

Cost of the preparation

The preparation of the pudding occupies only 3 to 4 working hours, so we employ the same

* The paste should be first added to the gruel and the wheat flour added right at the end. Otherwise, the preparation may not set properly.

staff for both this preparation and that of soya-bean milk and curd. After making due allowance for the proportionate expenses, materials used, depreciation on value of equipment, supervision, provision for unforeseen expenditure at 15 per cent and margin of 6 per cent as profit, the cost would work out to about one anna per pound. This would not include the cost of transporting the gruel (which is collected and delivered free by the kind courtesy of the army authorities) or distribution of the pudding to the different schools. Even after providing for these at one pice per pound, the cost is still attractive. The cost per child would work out to about $7\frac{1}{2}$ pices which is quite modest.

In the beginning we had to contend against a good deal of prejudice, but the product soon became steadily popular. Although we are using gruel from parboiled rice, the final product has nevertheless an attractive flavour and taste corresponding to that of more expensive preparations served in restaurants.

Possible improvements

The preparation is deficient in fat, the main source of this constituent being only the added soya paste (after extraction of milk) which contains 2.5 to 3 per cent oil. Extra fat in the form of deodorized oil, vanaspati or ghee would be rather expensive. About 1.5 pices per child would be about the minimum required to increase the fat content by about 1 per cent. Addition of a savoury would provide a good supplementary dish, but this, again, would add to the cost.

The children receiving the pudding are under the observation of the health authorities. Systematic records will soon be available. The pudding has also been fed to experimental animals and has been found to have a useful supplementary value when added to poor rice diet.

Gruel is still wasted. Other cities can produce similar preparations

The conditions of the preparation have now been standardized and the operations reduced to a routine. It should now be possible to start similar production at other centres as well. The gruel can be collected from any of the big feeding centres where rice is eaten. With proper organization, many big towns can produce substantial quantities of a clean, wholesome food material which can be fed either to the poor or to young school children who will eat it with much relish and benefit.

The above investigation would not have been possible but for the keen interest and enthusiasm of Mr. P. M. Jayarajan, Collector and Controller of Civil Supplies, Civil and Military Station, Bangalore, to whom our warm thanks are due. Our thanks are also due to Messrs. M. N. Srinivasa Iyengar and E. S. Krishna Iyer, who helped actively in the preparatory work and supervised the production.

UNDERGRADUATE TEACHING OF ANATOMY

By A. M. KHAN, M.S. (Anatomy), M.S. (Surgery),
F.R.C.S. (Eng.)

Professor of Anatomy, King George's Medical College,
Lucknow University

- A. Introduction.

A. Introduction

SINCE publication of my (Khan, 1945) previous paper on 'The Organization of Anatomy Department' I have discussed this and allied topics with eminent anatomists in Britain, France, Switzerland, Canada and U.S.A. during my one-year tour in the West. Those who have completely endorsed the views expressed in this paper constitute a remarkable majority. The dissenting minority differed not on principles but in details. These principles have received unqualified recognition in the Bhore and Goodenough Committee Reports also.

The subject of the present paper, the standard and methods of teaching of anatomy to undergraduates, is a vital problem in medical education and has been dealt with extensively at special conferences and in the correspondence columns of the *British Medical Journal*, Society Addresses and Association Meetings since 1935. It was my privilege to discuss certain details in this connection with no less than twenty teachers in the West. What follows is a constructive analysis of all I could assimilate during this tour.

The trend of our conversation varied from country to country as the system of teaching anatomy and the time devoted to it differs in many respects in each country. To mention the time factor only, two academic years are spent in U.K. and Canada, and only one academic year in many schools in U.S.A. and U.S.S.R. Variation in time factor alone implies difference in the standard of knowledge of anatomy considered necessary for proceeding to clinical studies in different parts of the world. Such difference is attributable to the different methods of teaching as well as the influence of the tradition of the mother countries, France and England, over the system of medical education in the daughter countries. French school was the model for medical education in U.S.A. and English schools influenced the design of Canadian and Indian institutions. In Canada, the Toronto University gave in 1944 a lead in remodelling its system of medical education on American lines. At the Toronto school, teaching of anatomy is completed by the end of the first term of the second year. Dissection of head and neck is carried out in the second year

while other parts are dissected during the first year. Clinical teaching begins from the second term of the second year. It is desired to bring the standard of medical education, like the value of the Canadian dollar, at par with U.S.A. system in due course. Strong opposition prevails against this move in other parts of Canada on the plea of weakening the foundation of medical education and perpetuating the gap between it and the superstructure of clinical instruction. It must be pointed out that dissatisfaction prevails even in U.S.A. against the atlanticized continental methods. Some of the European schools are still the best.

On my return from America to England, I discussed the subject again with English teachers in the light of experience gained in the New World. Most fruitful discussions took place at the Royal College of Surgeons, London, with Professor F. Wood Jones, professor-elect and Professor Cave, the outgoing professor of anatomy at the college. Professor Jones (1942) maintains along with many others that teaching of anatomy must extend over two academic years. They are equally emphatic that access to clinical material must be arranged from the beginning of the second year to impart a living touch to the teaching of anatomy and to emphasize the importance and application of anatomical principles to clinical practice. The consensus of opinion is in favour of regarding the second year as the 'bridge' or the intermediate class between the hitherto water-tight compartments of preclinical and clinical courses—a very vicious division indeed as the following criticisms will bear out.

B. Criticism of existing standard and methods of teaching of Anatomy

This subject was discussed at some length in my previous paper. However, reference to the following important points will not be out of place:—

1. That two academic years are spent over the teaching of gross anatomy in cadaver houses by academic anatomists.

2. That the time spent in the teaching of cadaveric anatomy exceeds that spent on any other subject in the medical curriculum.

3. That knowledge of details of topographic anatomy thus learnt serves no useful purpose in the clinical training or future career of the vast majority of undergraduates who will go out in general practice.

4. That such details are consequently forgotten at the earliest opportunity without serving the purpose of even those who wish to proceed to postgraduate study.

5. That no undergraduate standard is maintained in the teaching of anatomy, unlike the practice in vogue in respect of other subjects of the medical curriculum. A graded standard for under and postgraduate courses is also the

accepted principle in the study of other Science and Arts subjects.

6. That no attempt is made during the preclinical period to teach the application and importance of anatomical knowledge to clinical work, thus defeating the very object of learning anatomy.

7. That the gulf between the preclinical and clinical studies, therefore, remains too wide and accounts for the ignorance of the undergraduate in respect of clinical anatomy.

8. That teaching of clinical anatomy is not carried out in the senior classes by teachers of anatomy, who are best suited to do so, with a view to emphasizing the application of anatomical principles to the diagnosis and treatment of individual cases. The following quotations from representative opinion will substantiate the abovementioned comments: 'We are of the opinion that the usual curriculum for anatomy which is followed at present is partly determined by traditional ideas which are no longer valid, and that it requires revision in certain directions. Much of the anatomy which the medical student is commonly required to learn is concerned with topographical details of importance only to the specialist and we believe such details are quite unnecessary for the ordinary medical student who is working for the preclinical examination' (Appleton, Boyd, Clark, Hamilton and Whillis, 1942).

Referring to the above letter, an eminent correspondent remarks:—'*The defect is shown by the profound ignorance of the majority of students beginning their clinical work concerning the aspects of anatomy which are of importance to the study of disease. In clinical teaching an anatomical question rarely elicits the proper answer*'.

'What is the nature of the defect in the teaching of anatomy which such a lack of knowledge suggests? Is it possibly a fault of the present system whereby medical students spend two years under teachers not in clinical practice, in departments of anatomy often widely separated in space, in administration and perhaps in spirit from the clinics to which students will proceed? I think it undoubtedly true that under this system teaching will tend to lack clinical perspective and will lead the students implicitly to regard anatomy as a subject unrelated to the study of disease, to be put aside with a sigh of relief on proceeding to clinical work'.

'Should this be so, a possible, if rather drastic remedy would be to eliminate the separate department of anatomy and the academic anatomist from the curriculum, and to present the anatomy "required by the general practitioner" during clinical instruction' (Jessop, 1942).

'No doubt that the structure of the body is the necessary foundation of our subject, but while we can name off-hand many admirable doctors can we guarantee one who could map out the anastomosis round the knee-joint, or its

capsular and muscular attachments? No: a good doctor does not need such details or to know the cranial foramina and what each transmits. To no advantage are the student's youthful years busied with such structural details' (Adams, 1942).

'It is laid down in the existing regulation that elementary methods of clinical examination including the interpretation of physical signs, the use of the stethoscope and ophthalmoscope, and introduction to general Pathology and Bacteriology should be taught in the preclinical period. It has hitherto not been possible in most universities to arrange for this teaching up to the required standard' (Health Survey and Development Committee Report, Vol. III, p. 111).

C. Modern trends in teaching of Anatomy

1. That in view of the future requirements of the undergraduates principles of anatomy should be taught instead of minute details.

2. That cadaveric anatomy should be regarded as the means and living anatomy as the end of teaching the subject.

3. That living anatomy should comprise of:—

(a) Surface Anatomy including minor endoscopy.

(b) Radiological Anatomy including fluoroscopy and demonstrations on plain and contrast radiograms.

(c) Clinical Anatomy including introduction to clinical methods.

4. That principles of embryology with reference to congenital defects should be taught instead of details of embryology.

5. That, in addition, principles of post-natal growth should also be taught in relation to nutritional and hormonal disturbances. Emphasizing the necessity of including post-natal growth in the curriculum, an eminent anatomist remarks: 'It has always been an anomaly that the student should be given opportunities of acquiring a good knowledge of antenatal development and of the anatomy of the adult, but little or no attempt should be made to bridge the gap between' (Johnston, 1942). Following quotations from representative opinion will bear out the general trend:—

'Dissection of every part is unnecessary; sound knowledge can be obtained by other methods in association with a limited course of dissection' (British Medical Association Committee on Medical Education).

'G. P. needs to know in general way and not details which anatomists and surgeons should know' (Adams, loc. cit.).

'At one time hospital attendance and dissection ran concurrently; departure from this has been a disadvantage. Bearing this in mind I have arranged patients to be presented to senior students. Much closer co-operation between anatomical and clinical study is needed; anatomists might be attached to the staff of hospitals in order to make this possible' (Dow, 1942).

'In most universities principles and practice are placed on opposite poles so that when the student reached his practice he had forgotten his principles.'

'Whole body should be dissected but less details expected from the students.'

'During the later years of the curriculum, special courses in anatomy should be arranged in association with final years subjects' (Dow, 1942, and Indian Medical Council).

'In teaching and in learning what we want is more of the *why* and *wherefore* type of anatomy and this should begin right from the start in the early days of undergraduate training and not be left as an addendum to be taken up in the later years of the curriculum.'

'Learn anatomy and then apply it' is the attitude of many. We would say 'Apply anatomy while you learn it, because until you can apply it you really haven't learned it' (Kirk, Middlesex Hospital, London. Paper read before Association of Surgeons of Great Britain and Ireland, 2nd May, 1945).

'Every effort will be made to exemplify this principle by the inclusion of clinical teaching in the preclinical period, given by a clinician who will bring living reality into what often tends to be a dead and purposeless study. Similarly the teaching of preclinical subjects will not end with the passing of examinations but will extend into and throughout the clinical years by regular courses given not informally by clinicians, but by regular teachers in the preclinical subjects' (Bhore Committee Report, Vol. II, pp. 356-7).

'During the last two terms of the intermediate period the gap between the intermediate and clinical studies should be bridged by examples of the applications of physiology and anatomy to clinical medicine and surgery and by an introductory course illustrating the principles of general pathology, immunology and bacteriology. With this object it is desirable that a member of the staff of the Department of Anatomy, Physiology and Pathology should be afforded free access to the clinical material of the hospital—or, alternatively, that a member of the staff of the hospital should be attached to each of the departments. This proposal is made not with a view to initiating the student into the problems of clinical medicine but to enable him by the demonstration of the application of physiology, anatomy and general pathology to the study of medicine to appreciate the relevancy of his laboratory observations and experiments to the structure and function of the living human body' (Report of the Conference of Representatives of Oxford, Cambridge and London Universities and Royal Colleges on the Medical Curriculum, London, 30th April, 1935).

D. Proposed standard of teaching Anatomy

Perusal of the criticism of existing standards and methods as well as the modern trends in

different countries should leave no doubt in the mind of any one that there is an urgent need to set our house in order. To implement such reforms as are envisaged by individuals and committees already referred to a few suggestions are offered in the following paragraphs :

At least 90 per cent of the undergraduates qualify to engage in general practice. While no detail is too unimportant for the specialist it will suffice for the would-be general practitioner to be conversant with 'basic anatomy of the living'. Basic anatomy of the living implies knowledge of the development and structure of the body which will enable the undergraduate to understand the significance of congenital abnormalities, defects of post-natal growth, clinical signs and symptoms and help him in the prevention and treatment of diseases as a general practitioner. To be more explicit, basic anatomy should comprise of general principles of (a) embryology, (b) post-natal growth and (c) living anatomy of the adult. It appears necessary to illustrate the conception of 'principles' instead of 'descriptive details' with which the existing textbooks are stuffed.

Principles of embryology.—This should comprise a course of lecture demonstrations, illustrated by actual embryos, models and diagrams, emphasizing the process of differentiation in the embryonic disc which results in the formation of the rudiments of the nervous, alimentary, respiratory, circulatory, genito-urinary and skeletal systems. This should be followed by an outline of the development of each system, indicating the genesis of common congenital defects associated with each system, viz, spina bifida, tracheo-oesophageal fistulae, imperforate anus, undescended testis, polycystic kidney, hare-lip, cleft palate, etc.

Principles of post-natal growth.—This should comprise a study of the following aspects :—

1. General features of growth in relation to (a) cell division, (b) fuel supply, (c) environment and (d) heredity.

2. Classification of growth patterns :—

(a) *General type.*—Growth of the body as a whole, linear (stature), areal (surface area), ponderal (volume). Standards of height-weight ratio at different ages as required for the assessment of physical status.

(b) *Neural type* (brain, eyeball, etc.).—Rapid growth during infancy and childhood with a sharp transition to a slow rate up to maturity.

(c) *Lymphoid type.*—Rapid rise in infancy and early childhood, a continued increase to a peak about puberty and decline thereafter.

(d) *Genital type* (prostate, testis, uterus, ovary).—Slight increase in infancy; latent period lasting to the later part of the first decade; rapid growth throughout prepubertal period and adolescence.

(e) *Supra-renal type.*

(f) *Mixed type.*

3. Rhythm and rate of growth at various ages, its relation to sexual hereditary, hormonal, nutritional, environmental factors and disease.

4. Growth changes in the soft parts, viz, spinal cord, kidneys, urinary bladder, heart, lungs, etc.

5. Growth changes in the skeleton :—

(a) Progress of ossification and maturation with special reference to long bones, paranasal sinuses, mastoid process, arches of the foot, etc.

(b) Cessation and arrest of growth; outlines of determination of skeletal age and comparison with chronological age.

6. Correlation between physical growth and mental growth as assessed by I. Q. tests.

7. Retardation of growth, senescence and senility. Factors concerned in and biological significance of these phases of growth.

Principles of living anatomy of the adult :—

Skeletal system.—Detailed study of each bone has nothing to commend it. This remark applies with greater force to small bones of the hand, feet and the trunk than to the skull, long bones and the pelvis. Going back to the small bones, it is a favourite question in the oral examination to ask the side of a carpal or serial number of a rib which differs only slightly from the typical member of the series. To answer such questions a detailed study of these bones is required. What useful purpose can be served by mastering such details during clinical career or general practice I am at a loss to understand.

Comparative study of carpus *versus* tarsus and metacarpus *versus* metatarsus, training to recognize the bony landmarks presented by them in the living body and identify them in skiagrams is recommended. Attention should be drawn to sesamoid bones and accessory ossicles in skiagrams. Study of a typical rib and the grossly atypical ones should be combined with training to recognize them in the living and skiagrams.

Skull.—Bearing the utility consideration in mind, detailed knowledge of the individual cranial bones, except the temporal, is hardly necessary. Conception of the skull as a whole, relation of vertex to underlying brain and meningeal artery, and of the base to the exit of cranial nerves is much more important. Among the facial bones, mandible and maxilla deserve special consideration. Orbit, nasal cavity, paranasal sinuses, middle ear and its relation to mastoid process demand a detailed study.

Vertebral column.—Familiarity with a typical vertebra of each series as well as the grossly atypical ones, and with the nature of intervertebral joints, foramina, curvatures of the spine and how they are maintained is recommended. Sacrum deserves special consideration in relation to the pelvis and the anatomical variations at the lumbosacral junction.

Long bones.—Intimate knowledge of the long bones in terms of structure and function is

desirable. It is important to know the contour of their shafts and build of their articular ends. Growth changes, epiphyseal line, capsular reflection, angles, subcutaneous borders and curvatures of shaft merit special consideration. It is not enough to learn the dry bones. What is more important is training during the preclinical period to identify their salient features in the living, clinically and radiologically. The last recommendation should apply to the entire skeleton.

Neuro-anatomy.—It is important to know the functional anatomy instead of details of structure of the central nervous system.

Spinal cord.—The pattern of the structure of the spinal cord is essentially the same throughout. Grey matter is disposed in a continuous sheet around the central canal. It has somatic and autonomic components. The white matter surrounds the periphery and comprises of ascending and descending tracts. Only the important tracts need be taught.

Medulla, pons and midbrain.—Their structure admits of a common plan so far as disposition of grey matter in form of nuclei dorsally and white matter in form of tracts ventrally is concerned.

Cerebrum and cerebellum.—The neopallial grey matter is disposed on the surface while the phylogenetically older centres are represented in the buried nuclei. Shape, position, relation and function of such nuclei deserves attention. The ventricular system, subarachnoid space and the circulation of C.S. fluid deserve emphasis. The localization of 'functional areas' on the cerebral cortex and structure of the internal capsule must be learnt.

Peripheral nerves.—A knowledge of their origin, course, muscular distribution and sensory territory is important. While the sensory territory of a nerve trunk is of importance, it is futile to know every cutaneous twig arising from a nerve. As regards relations of nerves, details are unnecessary; emphasis should however be laid on the specially vulnerable sites in their course, viz, relation of radial and ulnar nerves to the humerus, lateral popliteal nerve to the neck of the fibula, etc. Importance of such knowledge should be emphasized at the bedside during the second year and throughout clinical training.

Cardiovascular system.—Teaching should aim initially at presenting the anatomical basis of circulation during foetal and post-natal period. Structure of the heart, its nerve, and blood supply, its position and relation to the body surface in the living, its apex beat and sound will receive the first consideration. Among the arteries, course of large vessels concerned in the systemic and pulmonary circulation will rank next. The undergraduate should be trained to delineate the course of superficial vessels in the living with the help of their pulsation and identify intra-thoracic vessels in skiagrams.

Among the smaller ones, lenticulo-striate, post-inferior cerebellar, middle meningeal arteries, etc., merit special attention.

Course of minute branches participating in arterial anastomosis is unnecessary. On the other hand principles of collateral circulation, effects of interference with circulation, and response of a limb, thus affected to temperature changes should be stressed. This can be done at the bedside or on experimental animals. It must be emphasized that it is more important for the undergraduate to know the application of that minutæ of structure, just as it is more important for him to know the action of sulphonamides than the mode of their action. 'Anatomy without physiology is dead; physiology without anatomy can have no meaning and pathology without anatomy and physiology would be a mystery' (Kirk, *loc. cit.*).

Veins.—Origin and course of important venous channels of the systemic and portal circulation should be taught. Anastomosis between systemic and portal circulation and the importance of such anastomosis must be emphasized in the living. Dural sinuses, their rôle in the absorption of C.S. fluid, their surface relations at different ages, their important tributaries including emissary veins and the importance of the latter should be stressed. Saphenous and cubital systems deserve special consideration. Mechanism of venous return, the effects of interference with such return and varicosity of veins must be brought home in the living. It is equally important to know the plan of vascular supply to muscle, tendon, joint capsules, synovia, nerve, skin and important viscera. Details of visceral blood supply which assume great importance to a surgeon are considered unnecessary for the undergraduate.

Lymphatics.—Instruction on parietal lymphatics with their regional nodes in the axilla or groin, and visceral lymphatics with their regional nodes in the abdomen, thorax and the neck as well as the circle of Waldyer should be given in a general way during the preclinical period. Study of the lymphatic drainage of individual organs should be stressed during the clinical years by teachers of anatomy.

E. Proposed methods of teaching Anatomy

Having considered the undergraduate standard in anatomy the next problem demanding attention is the method by which the undergraduate should be equipped with the requisite knowledge in the least time. In dealing with this aspect of the theme certain considerations based on modern trends must be borne in mind.

1. That since the undergraduate has to deal with the living throughout his life he should be taught, as far as possible, 'living anatomy' already defined.

2. That teaching of the principles of anatomy, which cannot be carried out on the living, must

be carried out on the cadaver; knowledge thus gained will be referred to hereafter as 'cadaveric anatomy'.

3. That 'living anatomy' is the end of teaching anatomy and 'cadaveric anatomy' is the means to that end.

4. That the undergraduate must be taught the importance and application of anatomical principles to diagnosis and treatment as early as possible. Such teaching must be carried out by teachers of anatomy throughout the clinical years.

In view of these fundamental considerations teaching has to be so organized as to equip the undergraduate with knowledge of 'principles of anatomy' which are of importance in the diagnosis and treatment of ailments that fall to his lot. In view of the vast majority going out in general practice, the requirement of anatomical knowledge for the class of general practitioners must receive priority in organizing teaching of anatomy. Such an organization must provide for graded teaching during the preclinical and clinical years and also bridge the most abrupt gap between preclinical and clinical periods. A happy compromise between current Indian methods, and those followed in U.N.R.A. and U.S.A., can be achieved by teaching the traditional 'Cadaveric Anatomy' as the basis during the first year and 'Living Anatomy' during the second as well as subsequent years of the medical curriculum. The whole of the second year can thus be utilized as a link between cadaveric and clinical teaching.

Cadaveric Anatomy in the first year

As explained already this refers to anatomy learnt from the study of bones, dissected parts and actual dissection performed by the undergraduate himself. While dissection provides unique opportunities to study the structure of the human body in detail there are certain inherent defects in it from the viewpoint of the undergraduate :—

1. The existing system consumes over 1,000 hours of the preclinical period on anatomy and appears to be the greatest defect in the education of the undergraduate in India. Some of this time could certainly be spent better on pathology and preventive medicine.

2. The viscera of formalin—hardened cadavers give a distorted picture of the living structure.

3. The undergraduate does not require the details thus learnt for successful practice of his profession as a general practitioner. Keeping in view the abovementioned objections to the two-year course of cadaveric anatomy, taught by academic anatomists, it is highly desirable to modify the method as to permit completion of such course within the first year, thus sparing the second year for commencing the study of 'Living Anatomy'. The following method, as practised in this university, is suggested :—

Demonstration on a bone should go side by side with the study of related soft-parts previously dissected. This is to be followed by demonstration—dissection by a teacher on the same region whenever parts are available with a view to setting the undergraduate's bearing for independent dissection. Finally, the student dissects the very part the bone and soft tissue of which he has already studied.

The method holds good for the extremities, head and neck and to a limited degree for the brain and the abdomen. No time is wasted in dissecting out cutaneous nerves or veins as the latter are best studied in the living. Special features of deep fascia are studied in the course of dissection. The plan on which deep dissection is carried out is based on the methods followed in U.S.A.

The undermentioned schedule is followed by the first-year students in this university for dissection and lecture demonstrations on the lines indicated above. Division into batches dissecting different parts is unavoidable due to paucity of cadavers :—

August to November	Superior extremity, thorax, inferior extremity, brain (by rotation).
December	.. Revision and class test.
January to March	.. Abdomen and head and neck.
April	.. Revision and class test.

Students attend lecture demonstration for one hour and dissect for three hours on every working day. There are 184 working days in each session. Thus, theoretically 736 hours are required to complete the study of cadaveric anatomy. Making allowance for Saturdays, casual holidays and change-overs, this time does not exceed 600 hours of solid work in the department of anatomy. Since the entire body is dissected at full speed, considerable time is required to assimilate the text. Taking into consideration the time taken up by physiology, teaching of other aspects of anatomy during the first year is not considered desirable. However, a course on general embryology is given in this university in the form of lecture demonstrations for two hours out of the six hours didactic teaching per week during the early part of the session.

Living Anatomy in the second year

'To recognize the absence of the pathological is often just as valuable as to detect its presence.' (Kirk, *loc. cit.*)

That the undergraduate must learn 'Living Anatomy' to facilitate his clinical training and practice in future has received universal acceptance. What constitutes living anatomy and how it should be taught still remains vague to many. I utilized every opportunity to discuss these points with members of the craft abroad and had many surprises while talking to a number of seasoned anatomists. Professor Wassermann of the Chicago University, a German refugee in U.S.A., held very clear views on 'living anatomy';

but preferred to use the term 'functional anatomy' instead, as he laid emphasis on the teaching of the function of each structure. Some thought that 'living anatomy' implied only surface anatomy; others took it to be synonymous with 'radiological anatomy'. A good many were in favour of using this term for anatomy learnt from clinical cases, viz, hare-lip, cleft palate, hernia, nerve palsies, etc. A careful analysis leads me to the conclusion that living anatomy should comprise of the following:—

1. Surface anatomy including identification of subcutaneous structures, relation of viscera to body surface, endoscopic appearance of easily accessible cavities—nasal, oral, aural, etc.

2. Radiological anatomy.—Anatomy learnt by fluoroscopy, plane and contrast radiography of normal structure.

3. Clinical anatomy.—Anatomy learnt from clinical cases by using clinical methods instead of the scalpel and dissecting forceps.

The teaching of clinical anatomy in the second year of the preclinical period is a recent innovation and its importance has been emphasized under different names on many occasions by individuals and expert committees—Goodenough Committee in England, Indian Medical Council and Bhore Committee in India, several medical faculties in U.S.A., etc. Unfortunately detailed reasons have not been given in support of this move. Nor have these reports received enough publicity. These facts coupled with the apprehension of clash against vested interests and the conservatism of people trained in cadaver houses have stood in the way of urgently called-for reforms in undergraduate teaching in anatomy. An attempt is made in the following paragraphs to substantiate the necessity of access to clinical material in the teaching of this subject on modern lines.

Necessity of teaching Clinical Anatomy in the second year

There is no objection to the teaching of living anatomy on the normal in any quarter but encroachment by the abnormal is seriously objected to by a few clinicians and academic anatomists. Whatever their reasons against teaching living anatomy on the abnormal or so-called 'clinical anatomy' be, my arguments for insisting on doing so are based on the following desiderata:—

1. To bridge the gap between cadaveric study and clinical requirement.

2. To emphasize the importance and application of anatomy to clinical study and practice.

3. To emphasize the normal by contrast and comparison with the abnormal.

4. To teach those aspects of anatomy which cannot be taught on the normal, viz, lymphatic system, muscle functions, congenital defects, etc.

5. To bring teaching of anatomy in alignment with the requirements of clinical training and practice.

6. To impart a 'living and practical touch' to the teaching of anatomy.

7. To give the undergraduate a chance to distinguish between 'applied anatomy' and 'gross anatomy' at the proper time.

8. To develop in the undergraduate the power of observation to differentiate between the normal and abnormal at the earliest opportunity.

9. To turn out at the end of the First M.B.B.S. course 'embryonic clinicians' instead of 'cadaveric anatomists'.

10. To save two months' time of the undergraduate hitherto spent in certain universities over so-called 'preclinical classes' taken just an hour a day by most junior residents to baptize those freshly promoted from the cadaver house to the hospital for more serious clinical work. I fear such classes were devised to comply in letter with a recommendation of the Indian Medical Council for including an introduction to clinical methods during the second year of the curriculum with a view to facilitating teaching and learning of living anatomy. Most of the abovementioned reasons are too obvious to merit an explanatory note. However, a few general remarks will not be out of place to clarify the issue.

Bridging the gap.—The official method of teaching anatomy in many Indian universities aims at producing a cadaveric anatomist in two academic years in the pious hope of his resuscitation to life in the teaching hospital. This practice is based on bitterly criticized British traditions which owe their existence to the late addition of preclinical departments to fully-grown voluntary hospitals not under university administration. An overnight jump from the glass chamber of the cadaver house to the hospital incubator is a big performance indeed and successfully evades any possibility of emphasizing the relation of anatomy to disease by teachers of anatomy who are best suited to do so. What a sad commentary indeed!

The extent of the existing gulf between conveniently called preclinical and clinical studies can be easily gauged by taking into consideration what the undergraduate learns during the pre-clinical years and what he is required to know to facilitate his clinical training. Briefly, the undergraduate is taught during his preclinical years all details of cadaveric structure of the following:—

- (a) *Heart*—except training to localize the apex beat and detect its normal sounds.

- (b) *Lungs*—except the nature of respiratory sounds.

- (c) *Liver, spleen and kidneys*—except training to locate them in the living.

- (d) *Spermatic cord*—except its feel in the normal living.

- (e) *Arteries*—except that they pulsate and such pulsation is helpful in locating them and testing their patency in the living.

(f) *Neuro-anatomy*—except that it is related to signs and symptoms, *viz*, pain or anæsthesia, motor or vasomotor paralysis, visceromotor and viscerosensory reflexes, etc.

Knowledge of the 'exceptions' is undoubtedly the ultimate goal of learning anatomy. If so, is there any reason why the existing gap between the 'starting point' and the 'goal' should not be bridged? It is equally certain that the second year of the curriculum is the ideal period for bridging this ghastly gap.

Importance and application of anatomy.—The undergraduate in medicine has to learn anatomy with a definite aim, unlike the undergraduates in some other faculties, who learn their subjects just to obtain a passport for a career in which knowledge of the subjects studied may not be required. The aim of the medical undergraduate in learning anatomy is to develop a life-long familiarity with the application of anatomical principles to diagnosis and treatment. The present system of teaching cadaveric anatomy without any reference to the importance and application of the 'bundle of facts' taught, therefore, amounts to an utter disregard of the undergraduate's aim. It has been argued that their attention is drawn to the applied aspects of anatomy later—in the two months' preclinical course and regular clinical work.

Admitting that 'clinicians do so in senior classes, the objection that anatomists do not get a change of doing so at the most opportune period in junior classes stands very boldly. There can be no doubt that this responsibility devolves primarily on the anatomists who are expected to prune undergraduate teaching in a way refitting the future requirements of their pupils instead of burdening them with gross details of cadaveric anatomy. Can the anatomists do any better in their cadaver houses in spite of best intentions to do so? The answer is too obviously in the negative.

To justify the two years' course of cadaveric anatomy it has also been argued that undergraduates cannot follow application of anatomical principles without knowledge of pathology. The reply is simple: anatomical principles are being confused with pathological principles. It must be realized that before a proportionate blending of anatomical, physiological and pathological principles occurs in the subconscious mind of the undergraduate to evolve consciously a diagnosis or line of treatment, he must be taught separately the application of the principles of the three sciences named above at the bedside. Teaching of gross details to undergraduates in a cadaver house at the expense of the application of anatomical principles at the bedside defeats the very object of such teaching. Hence there is no justification for a two years' course of cadaveric anatomy in the undergraduate curriculum which lacks at present any provision for correlating anatomy with clinical work.

Emphasis on the normal by comparison and contrast against the abnormal

Teaching of gross details of cadaveric anatomy for two years is justified on the plea of imbuing the undergraduate with knowledge of normal structure. His ability is tested by questions on topographic details which shall seldom be of any help in his future career. *Is any attempt ever made to test his knowledge of the normal in the living?* No: The only way it can be done is to present to him abnormal cases and ask him to pick up the normal side in case of bilateral structures, *viz*, limb bones, testis, vas deferens, subcutaneous inguinal ring, etc. In case of unilateral and symmetrical structures, the same purpose can be achieved by comparison between a normal individual and a patient or between normal and abnormal films. In clinical work the decision between normal and abnormal has to be made invariably in the living. Knowing that such a decision becomes sometimes difficult even at a post-mortem examination, it must be realized that it is many times more difficult to make this distinction in the living. This is all the more reason that the student of anatomy must be made familiar with the appearance, feel, position, size, sound and radiological appearance of normal organs in the living. Such a training can be initiated on the normal but how can the conception of the normal be verified unless the abnormal is also available for comparison. To facilitate such comparative study access to abnormal material is indispensable. While the clinician needs clinical material to demonstrate the process of diagnosis, the anatomist needs it for emphasizing the normal by contrast and comparison.

Study of the normal by reference to the abnormal.—The following aspects of anatomy cannot be taught satisfactorily either on the cadaver or normal living subject:—

(a) Lymphatic system.

(b) Muscle function.

(c) Neuro-anatomy.

(d) Congenital defects and abnormalities of growth.

(a) *Lymphatic system.*—Importance of the study of the lymphatic system can hardly be over-emphasizing. Since it cannot be studied in the normal, clinical demonstration becomes inevitable. This is the only way it can be impressed on the undergraduate that the groups of nodes described in their books do exist in the body. Such a study will have to be a living study and a single demonstration of such a nature is worth more than many didactic lectures. Cases will also demonstrate the importance of such knowledge.

(b) *Muscle function.*—Muscle action cannot be learnt in the cadaver. Cramming of muscle action, as given in textbooks of anatomy, is a colossal waste of time since never one muscle acts singly in the living. It is not so much the action of individual muscles as the function of

group of muscles that is of real importance. In the normal subject when the primary movers come into play, other group of muscles, synergists and antagonists play their part as well, and it is wellnigh impossible to judge the function of individual or group of muscles. Further, any attempt to demonstrate such function on the normal does not create any impression on the undergraduate regarding the importance and application of the knowledge of muscle function. However, the only way that the undergraduate can be impressed with 'practical knowledge' is by demonstration on (a) normal individual subjected to electrical stimulation of their nerve trunks and (b) cases with nerve or muscle lesion. He can be made to test muscle function and tone for himself in the course of such demonstrations and the teacher can emphasize the anatomical basis of disturbed function and tone as well as the importance of such knowledge in re-educating muscle control by remedial exercises.

(c) *Neuro-anatomy*.—It is the functional anatomy of the central nervous system that the undergraduate is expected to learn. He does the spade-work by dissecting certain areas of the cerebral cortex, internal capsule, nuclei of the brain stem, etc. Such dissection gives no idea of their importance or their function. No amount of lecturing will leave a more lasting impression than demonstration on neurological cases. If cadaveric anatomy can be made so lively and interesting by such demonstrations, why should the undergraduate be condemned to cadaver houses while learning anatomy? 'The demonstration of a hemiplegic patient will teach a student many facts about the physiology and anatomy of the pyramidal tract which cannot be learned in any other way' (Report of the Conference of Representatives of Universities and Royal Colleges).

(d) *Congenital defects*.—While teaching principles of an embryology the teacher has to refer to hare-lip, cleft palate, branchial cyst, spina bifida, club feet, etc., to emphasize the importance and application of embryology. What impression will these terms convey to the undergraduate who has never seen such cases? He cannot appreciate at all what they signify. Models, diagrams and photographs improve the position but can they replace actual cases? To make the study of the subject interesting and practical recourse to clinical material becomes inevitable. Development of a clinical perspective and proper outlook in the undergraduate towards application of embryology is much more important than knowledge of 'blank' gross details.

Post-natal growth.—Knowledge of principles of post-natal growth is as important as those of embryology. Normal growth is considered such a natural phenomenon that it is hardly considered of any consequence by many; this is the main reason why post-natal growth has not been paid

the attention it deserves. The only way it can be emphasized is by demonstration on abnormalities of growth—stunted or accelerated growth, lapsed union, osteochondritis, achondroplasia, metaphysial aclasis, genu varus or valgus, postural scoliosis, faulty dentition, etc.

Bringing anatomical teaching in alignment with clinical needs

Knowledge of anatomy is required for the following purposes:—

1. To interpret signs and symptoms.
2. To perform clinical examination and detect an abnormality.
3. To evolve a diagnosis with the help of other investigations.
4. To institute proper line of treatment.

If the scope of anatomy is so wide why should its teaching be confined to cadaver houses? Obviously it must spread throughout the medical curriculum to give the undergraduate maximum benefit of the department of anatomy. Having acquired the knowledge of cadaveric anatomy in the first year the time of the undergraduate in the second and later years can be best occupied with diversion of his knowledge along the channels in which he will find a practical application of such knowledge. The subject is dealt with item by item.

Signs and symptoms.—To interpret signs and symptoms correctly it is essential to know their anatomical basis. Among such symptoms and signs may be mentioned, visceral and articular pain, local or referred, hyperæsthesia, protective rigidity and spasm of muscles, including limitation of excursion of diaphragm, wasting of muscles, alteration of reflexes, etc. It is equally important to know the anatomical basis of Trendelenburg, Moynihan's, Rovsing's signs, etc.

Clinical examination.—Knowledge of the body as a whole is a necessary preliminary to such investigation. Teaching on body types, variation in the position and shape of viscera associated with each type and training to recognize them must receive the attention they deserve. The practice of cramming details regarding surface marking of normal viscera leaves much to be desired. The standard landmarks based on averages and recommended by textbooks for this purpose most certainly do not apply to every normal individual. This can be best illustrated by referring to the heart; some hearts are placed transversely while others occupy a vertical position; how can the standard methods of marking the heart be compromised with its variable position? Moreover, the stereotyped methods of learning anatomy fail to provide the clinical perspective which is much more important than details of gross anatomy. Hence 'living anatomy' must be learnt on normal and abnormal subjects by resorting to clinical methods.

If routine teaching is modified on the above lines it is bound to change the outlook of the undergraduate and is calculated to prepare a

solid foundation for a scientific instead of an empirical clinician—the latter only knows that pain and vomiting are symptoms of appendicitis while the former is conversant with the anatomical basis for different signs and symptoms of the disease.

Diagnosis and treatment.—The importance and application of anatomical principles to the diagnosis and treatment of individual cases should be emphasized during clinical years by teachers of anatomy who must have free access to clinical material for the purpose.

Proposed schedule of teaching for the second year

Principles of anatomy	..	2 hours per week
Regional embryology (in batches)	..	1 hour per week
Post-natal growth (in batches)	{	1 hour per week (alternately).
Radiological anatomy (in batches)		
Surface and clinical anatomy (in batches).	..	2 hours per week
Prosector's duty	..	6 hours per week
TOTAL	..	12 hours per week

The above scheme is based on two hours' work per day in the second year as against four hours' work in anatomy during the first year. The two hours' time thus spared per day during the second year can be utilized for the teaching of additional subjects as recommended by the Indian Medical Council, viz, Principles of General Pathology, Elementary Bacteriology and Preventive Medicine.

F. Subsidiary recommendations

To introduce reforms in the teaching of anatomy on the proposed lines the following measures must be taken:—

1. Revision of the terms of appointment of the staff.
2. Preparation of textbooks on basic anatomy.
3. Installation of a diagnostic x-ray plant in the department of anatomy (Lucknow University has already done so).
4. Reorganization of the system of examination.
5. Teaching of clinical anatomy in senior classes by teachers of anatomy.

Terms of appointment of the staff.—The existing defects in the teaching of anatomy are undoubtedly an outcome of one of the conditions on which senior staff of this department is appointed—complete divorce from clinical work in spite of their being capable of doing such work. This condition may be an advantage to those teachers who desire to become academic anatomists for reasons of health or aptitude; but the poor students have to pay a very heavy premium on their education under such teachers. In the light of modern trends in teaching there is no place for such anatomists on the staff of institutions where undergraduates are trained.

There is yet another way in which the existing terms of appointment affect the cause of medical education adversely. This is by causing dissatisfaction among highly qualified teachers of

anatomy who quit the department at the earliest opportunity to take up more paying appointments on the clinical side. So far as Lucknow University is concerned, 11 out of 12 permanent teachers of this department can be called 'deserters'. The same holds true for several other universities. For these reasons there is dearth of suitably qualified teachers of anatomy in this country.

I am at a loss to understand the rationale underlying the existing term of appointment. Perhaps the idea is to spare the senior teachers of anatomy for wholtime research. As pointed out in my previous paper it is not possible for all academic anatomists, confined perforce to cadaver houses, to do any useful research unless they come in contact with human problems. The problem differs with the worker's experience and qualification. Why should his opportunities for work not differ? Under the present conditions there is every justification for suggesting a complete overhaul. However, a happy compromise between the two extremes will be to recruit 50 per cent of permanent staff on the condition of doing part-time clinical work. This principle has been in force in certain Indian universities, for years in respect of the departments of pharmacology and pathology. I know of other institutions in India and abroad where anatomy and physiology teachers are similarly governed. There is a strong case for universal adoption of this principle.

I have carefully studied the recommendations of the Bhore Committee on the subject and find it difficult to agree with them *in toto*. In fact their very approach to the problem is not above criticism. By recommending a senior liaison officer between clinical and preclinical studies as an additional hand they have failed to realize that the new hand, however brilliant, cannot change the 'cadaveric tone' of the entire department. Moreover, it will not be possible for one man to do the amount of work that teaching of the application of anatomy to different branches of medicine entails. Surgical, medical, ophthalmic and gynaecological anatomy cannot be taught by one person. Assuming that ophthalmic and gynaecological teaching will not require separate teachers (as much of it can be taught with medical and surgical anatomy) I consider it very important to have two separate persons. All this will involve extra expenditure and yet perpetuate the nineteenth-century condition of anatomy departments. However, such an arrangement is certainly justified where my suggestion is not practicable for immediate adoption due to the teachers of anatomy not being qualified to perform clinical duties. It follows that wherever they possess the experience and qualifications prescribed for holding senior clinical appointments, and several of them do possess, they must receive preference over raw additional teachers. This may amount to reversion to an old practice, yet this is the only way that frequent quits from the anatomy

department can be prevented and research as well as teaching in anatomy can be improved.

This suggestion is in keeping with the basic recommendations made by the Conference of Representatives of Universities and Royal Colleges in England in 1935 and conforms to the practice in vogue in certain institutions in this country as well as in the West. Senior teachers of the department of anatomy in association with junior ones should form a Clinical Anatomy Unit. Such an unit must hold full charge of beds in the hospital attached to the teaching institution according to the experience and qualifications of the chief. Their teaching experience in anatomy must be considered an additional qualification, and not a stigma, for holding a part-time clinical appointment if the person is otherwise qualified to do so. In case it is not possible to have two units in the anatomy department the purpose in view can be served by posting the Clinical Anatomy Unit on the surgical and Clinical Physiology Unit on the medical side of the teaching hospital. It must be pointed out that no useful purpose will be served by attaching, as recommended by the Bhore Committee, only a junior demonstrator of anatomy to the hospital or associating a part-time 'clinician of the status of a registrar' with an anatomy department where all the senior teachers continue to be academic anatomists and can teach only cadaveric anatomy. The demonstrators or registrars in India are only fresh graduates with rusty knowledge of anatomy and no teaching experience. Obviously the recommendations of the Bhore Committee are based on the old conception of cadaveric anatomy being taught by academic anatomists completely divorced from the teaching hospital. In view of the pendulum of current opinion having swung in favour of teaching 'living anatomy', their recommendations appear to me as very much out of date.

Preparation of textbooks

The necessity for the proper textbook is a real problem. The older ones have had their days. Among the modern ones, *Anatomy for Medical and Dental Students* by Mainland, Dalhousie University, Halifax, Canada; *Practical Anatomy* by Le Gros Clark, Oxford; *Surface and Radiological Anatomy* by Appleton, London, deserve mention. There is still a great demand for a new textbook written jointly by teachers in India. A work on Basic Anatomy including principles of embryology, post-natal growth and 'living anatomy' is a crying necessity. I wish this problem was taken up by the Indian Medical Council, in the absence of any association of anatomists, to standardize the teaching of anatomy in the country.

Reorientation of the system of examination.—The university examination should be held at the end of the second academic year.

1. *Written.*—Of the two papers on anatomy one should be allocated to questions on living anatomy and the other may conform to the old

pattern; or, alternatively, each paper may be modified to incorporate modern trends.

2. *Practical.*—Fifty per cent of marks may be assigned to the existing items—dissection and *viva voce* on bones, soft parts, as well as models. The balance may be earmarked for testing candidate's knowledge of living anatomy. This part of the examination should include questions on radiographs, surface and clinical anatomy. Candidates may be shown cases and asked to pick up the normal side, to explain the anatomical basis of signs and symptoms, mark out viscera by palpation, percussion, auscultation, etc.

Teaching of Clinical Anatomy in senior classes

One of the outstanding defects in the existing system is the lack of regular courses in anatomy by teachers of the subject during the clinical years in spite of specific recommendation by Indian Medical Council to that effect and their endorsement by the Bhore Committee. The necessity of such courses being given regularly can hardly be overstated. The proposed Clinical Anatomy Unit is best suited to conduct such courses. They should comprise bedside or outpatient and theatre demonstrations for two hours per week during the first two terms of third and fourth years and throughout the final year.

Summary and conclusions

1. That the standard and methods of teaching anatomy to undergraduates require immediate revision. The old conception of cadaveric anatomy being taught for two years as a preclinical subject by academic anatomists is untenable.

2. That the undergraduate standard should include principles rather than gross details of the development and structure of the body. The term 'basic anatomy' is recommended for the purpose.

3. That basic anatomy should consist of :—

- (i) Principles of Embryology.
- (ii) Principles of Post-natal Growth.
- (iii) Principles of Living Anatomy.

4. That living anatomy should be the end of undergraduate teaching and cadaveric anatomy the means to that end.

5. That cadaveric anatomy can be learnt during the first year in about 600 hours. Study of bones and soft parts should go side by side.

6. That living anatomy can be learnt during the second year in about 300 hours and should include :—

(i) Surface anatomy including minor endoscopy.

(ii) Radiological anatomy including fluoroscopy, plain and contrast radiography of the normal.

(iii) Clinical anatomy including introduction to clinical methods, *viz*, inspection, palpation, percussion and auscultation, with a view to correlating dissection with living anatomy and clinical work.

7. That teaching of clinical anatomy should be carried out in the hospital attached to the school by teachers of anatomy constituting the Clinical Anatomy Unit with effect from the beginning of the second year and last throughout the curriculum.

8. That modern textbooks are urgently required.

9. That the system of examination needs modifications.

10. That the two spare hours per day in the second year should be utilized for the study of elementary pathology and preventive medicine with a view to welding together the disjointed preclinical and detached clinical parts of the under-graduate curriculum.

11. That the introduction of the proposed changes will not only help in bridging the harmful gap between preclinical and clinical studies but will also permit the completion of courses in the senior classes about six months earlier. If vacations are curtailed, the entire medical course may not require more than four calendar years in view of overlapping in courses and concerted effort in teaching only fundamentals instead of details.

12. That the universities concerned are requested to introduce necessary reforms at the earliest possible opportunity.

USE OF HYDROGEN PEROXIDE AS A MILK PRESERVATIVE

By N. L. BANERJEE, M.Sc., A.I.C.

Assistant Professor, School of Tropical Medicine, Calcutta

[Read at the Indian Science Congress, Delhi, January 1947]

THIS work was undertaken at the instance of an official enquiry prompted by a commercial firm in order to know whether a limited amount of hydrogen peroxide can be used in preservation of milk for 48 hours longer than raw milk under ordinary condition. Under the Public Health Regulation now in force in the U.K. or India hydrogen peroxide has been classed as a non-permitted preservative in foodstuffs. Although

any kind of preservative in a foodstuff has been prohibited under the general restriction order, it is doubtful whether such a course is expedient in the case of hydrogen peroxide where a very small amount is necessary to preserve the milk with hardly any loss of its taste, quality and nutritive value. Besides, the chemical itself on remaining in contact with the organic matter of the foodstuff breaks up into nascent oxygen and water, leaving it quite harmless.

Specially purified metallic free hydrogen peroxide is now being prepared by electrolysis in some places in Italy. In many areas of this country milk is actually being treated by the chemical with success (Romani, 1944). Therefore there is no reason why this method should not be adopted in India where there is an acute shortage of milk in big cities like Calcutta. By treating it with a small dose of the preservative this valuable article of food can be brought here within 48 hours from many distant places where it is found in plenty and can thus solve the milk problem.

The practice of adding hydrogen peroxide to milk was in vogue long ago. Budde, the Danish Engineer, first thought of treating milk simultaneously with heat and hydrogen peroxide. The milk so treated is termed 'Buddeised milk' after his name. By this process one litre of milk is mixed with 15 c.c. of hydrogen peroxide solution of 3 per cent strength. The whole thing is heated for 3 or 4 hours continually at 51°C. The enzymes, viz, peroxidase and catalase present in milk, decompose the hydrogen peroxide into nascent and molecular oxygen respectively as well as water. The nascent oxygen and heat act conjointly to destroy the bacteria. The result is that we get a milk which remains fresh for 4 days (*vide table I*) without any loss of taste due to the addition of hydrogen peroxide. Yet the method is open to objection on the ground that it is not only impracticable from the commercial viewpoint, but that the continued action of heat and oxygen act deleteriously upon the vitamins present in the milk. Besides, the commercial hydrogen peroxide solution is likely to add poisonous impurities to the milk (Harvey and Hill, 1937). However, the variety of H_2O_2 solution that has been used in the experiment has been tested to be free of such impurities except a little citric acid and sodium salt. In order to avoid this sort of trouble as also instability of its strength, solid compound of hydrogen peroxide with urea has been prepared in the laboratory in the following way. This compound is perfectly stable in the dry state at ordinary temperature and its equivalent amount has been used in the experiment just as liquid H_2O_2 solution without any difference (*vide table II*).

Method of preparation

1.8 gm. of urea is dissolved in 30 c.c. of alcohol. To this are added gradually with gentle shaking 30 c.c. of H_2O_2 solution of 10 vol.

strength. A trace of citric acid is then added to the mixture for stabilizing the hydrogen peroxide. The whole thing is kept overnight in ice chamber. The alcohol from the mixture is then distilled under reduced pressure at ordinary temperature (35°C.). The residue is poured over a shallow dish and treated with a little absolute alcohol and left under electric fan to evaporate slowly. After a while beautiful, white prismatic crystals of urea peroxide, $\text{CO}(\text{NH}_2)_2$, H_2O_2 appear. These are drained as far as possible from the mother liquor and then washed with a little absolute alcohol to free them from impurities. They are then dried over calcium chloride under vacuum.

The strength of the crystal in terms of H_2O_2 has been determined to be 30 per cent (theoretical—34 per cent). The compound is hygroscopic. It decomposes at 60°C. into urea, water and oxygen. It is otherwise quite stable in the dry state and can be compressed into tablets. One gramme of the tablet dissolved in 10 c.c. of water produces H_2O_2 of 10 vol. strength. Each tablet weighing 16 grains is enough to keep a pint of milk fresh for 48 hours if kept in an open vessel. Any trace of H_2O_2 is hardly perceptible to the palate after the interval. It completely disappears on heating the milk.

TABLE I

Date of experiment—27th September, 1946
Finding the dose of H_2O_2 per 100 c.c. of raw milk

Nature of milk	Dose of H_2O_2 soln. (10 vol. O) in c.c. added to 100 c.c. of milk within 3½ hours of collection	Time of clotting
1. Raw cow milk (pure) ..	1.0	24 hours.
2. Do. do. ..	1.5	Do.
3. Do. (Buddesised)	1.5	4 days (closed bottle).
4. Raw milk (above) ..	2.0	3 days (open bottle).
5. Do. ..	3.0	18 days.
6. Do. ..	5.0	Not clotted after 20 days.
7. Pasteurized (Keventer)	5.0	21 days.
8. Do. ..	7.5	Do.
9. Raw milk (pure) ..	7.5	Not clotted after 20 days.

In order to find the minimum dose of H_2O_2 , 100 c.c. of the same raw milk of acidity 16° are taken, in several uniform conical flasks and treated with progressive doses of H_2O_2 of 10 vol. strength within 3 hours of milking cow. The flasks are plugged with cotton-wool and kept at laboratory temperature (85°F.) for observation. It has been found that with doses below 2 c.c. of the peroxide solution, the milk invariably curdles within and after 24 hours,

while the milk having this dose remains fresh for at least 3 days if kept in an open flask. The closed flask containing the dose just decomposes within 48 hours (*vide* table V).

Observation has also been made on Keventer's pasteurized milk as well as on raw milk with higher doses of the H_2O_2 solution, which keep it fresh for about 3 weeks. It has been calculated that roughly 2/5ths of an ounce of H_2O_2 solution of 10 vol. strength costing about ½ an anna is enough to keep a pint of milk sweet for 48 hours. One company is understood to manufacture it at 10 as. per lb. A graph has been drawn showing relationship between the doses of peroxide solution and the number of days to clot the milk.

Experiments were conducted to compare the action of the urea peroxide compound with that of the H_2O_2 of 10 vol. strength. 100 c.c. of the same raw milk were taken in each of the five uniform conical flasks. To the flask A is added 0.12 gm. of the compound equivalent to 1 c.c. of H_2O_2 solution. To the flask B 1 c.c. of H_2O_2 solution is taken. To the flask C 0.24 gm. of the compound and to the flask D 2 c.c. of the H_2O_2 solution are added respectively. The fifth flask O containing only milk serves as the control. All the flasks are plugged with cotton-wool and kept for 24 and 48 hours for observation. The results are as shown in the table. There is hardly any difference between the solid compound and its equivalent of H_2O_2 solution so far as keeping quality and taste are concerned. It is noticed that with the insufficient dose of either, no trace of H_2O_2 is found to be present, but peroxidase remains, while with the proper dose or above, H_2O_2 persists during the interval to the total destruction of the peroxide.

This experiment is performed with a view to knowing what effect the optimum dose, *viz* 2 c.c., produces on the raw milk after 48 hours so far as the analytical constants, vitamin A and vitamin C are concerned.

TABLE II

Date of experiment—27th November, 1946. Comparison of the solid urea compound with liquid H_2O_2 solution

Nature of milk	RESULT AFTER 24 HOURS			RESULT AFTER 48 HOURS			REMARKS
	Acidity	H_2O_2	Perox- idase	Acidity	H_2O_2	Perox- idase	
O. Raw milk (acidity 16°) ..	70° (curdled).	Nil	Present	Curdled	Nil	Present	
A. Do. c. 0.12 gm. of urea compd. (equiv. to 1 c.c. of H_2O_2) per 100 c.c. of milk.	19° (st. acid).	Nil	Trace	Curdled	Nil	Trace	Just decomposes after 24 hours.
B. Do. 1 c.c. of H_2O_2 soln. per 100 c.c. of milk.	21° (decomp.).	Nil	Trace	Curdled	Nil	Trace	Decomposes after 24 hours.
C. Do. c. 0.24 gm. of urea compd. (equiv. to 2 c.c. of H_2O_2) per 100 c.c. of milk.	16° (good).	Present	Nil	17°	Trace	Nil	Decomposes after 3 days.
D. Do. c. 2 c.c. of H_2O_2 soln. per 100 c.c. of milk.	17° (good).	Present	Nil	18°	St. trace.	Nil	Decomposes after 3 days.

TABLE III

Date of experiment—11th December, 1946. Effect of the optimum dose on the vitamins and the analytical figures

	Percentage of fat	Percentage of lactose	Vitamin C	Vitamin A	REMARKS	
Raw milk	5.8	4.44	0.25 mg. per 100 c.c.	0.7 I.U. per c.c.	Normal	
					Vitamin C 0.7 mg. per 100 c.c.	Vitamin A 2 I.U. per c.c.
Result after the addition of H_2O_2 soln. (2 c.c.)—						
(a) After 1 hour ..	5.8	3.91	0.14 mg.
(b) After 24 hours ..	5.8	3.90	0.11 mg. (cf. 0.19 mg.)	Raw milk
(c) After 48 hours ..	5.8	3.90	0.10 mg.	0.7 I.U.

It is found that the fat percentage remains unaltered but the lactose is lightly reduced due to oxidation; vitamin A remains unaltered, while vitamin C decreases by 44 per cent from the original value. In passing it is noticed that the raw milk under experiment is rather poor in both the vitamins compared with normal milk. The reason is that the cow is stall fed and not allowed to graze. In India the question of deriving vitamin C from milk is ruled out in as much as the people generally use milk after boiling. This destruction of vitamin C by H_2O_2 may, however, be compensated by taking supplementary food, e.g. orange juice, etc.

Experiments were conducted to note what difference it makes by taking milk in closed bottles as well as in open bottles with 1 c.c. and 2 c.c. of the H_2O_2 solution per 100 c.c. of milk. In table V the experiment was done in a confirmatory way. It was found that the milk in the open bottle kept longer than in the closed bottle and during the same period more acidity developed in the latter. The reason why this is

TABLE IV

Result after addition of different doses of H_2O_2 solution to closed bottle as well as to open bottle to 100 c.c. of milk

After 24 hours

	Dose of H_2O_2 soln.	Acidity	H_2O_2	Peroxidase
Open bottle	Nil (raw milk).	89° (decomp.)	Nil	Present
	1 c.c.	22° (curdles on heating).	Nil	Trace
	2 c.c.	16° (good).	Present	Nil
	After 48 hours			
	Nil (raw)	106° (decomp.)	Nil	Present
	1 c.c.	70°	Nil	Nil
Closed bottle.	2 c.c.	16° (good)	Present	Nil
	1 c.c.	73° (decomp.)	Nil	Nil
	2 c.c.	28° (curdles on heating).	Nil	Nil

The vitamin intake in Febrile conditions

The restricted diet associated with febrile illnesses involves a reduced intake of vitamins and minerals at a time when the heightened metabolic rate calls for an increase.

A multiple vitamin and mineral supplement (Complevite) is an essential addition to all such diets.

Supplying the full physiological requirements in this way offers the greatest likelihood of shortening the illness.

COMPLEVITE

The adult daily dose provides:—Vitamin A 4,000 i.u., vitamin B₁ 200 i.u., vitamin C 400 i.u., vitamin D 300 i.u., calcium 153 mg., iron 68 mg., trace minerals 3 p.p.m.

Further particulars concerning Complevite and Fertitol from Martin & Harris Ltd., Mercantile Building, Lall Bazar, Calcutta.

Products of Vitamins Limited, London, England.

FERTIOL (VITAMIN E and all the other factors of Wheat Germ Oil)

Used in the treatment of habitual abortion, sterility of dietary origin and certain neuro-muscular degenerations.

Fertitol is a highly active natural and stable source of vitamin E and of the other factors of wheat germ oil. Each 5 minim capsule is standardised to contain 3 mg. α -tocopherol.

Wheat germ oil has given better clinical results¹ in some trials and shown properties additional to those of pure α -tocopherol.

A treatment of TENOSYNOVITIS by means of Elastoplast

CASE HISTORY

On the 16th January a brick-layer, aged 31, complained of pain at the back of the wrist. It was particularly noticeable when grasping.

A radiograph revealed nothing abnormal, but clinically there was synovial crepitation in the extensors.

Treatment—Fingers immobilised by postero-anterior strips of Elastoplast binding them over a roller bandage. Another turn of Elastoplast bandage strapped the wrist.

On the 23rd January there was still slight pain and

Elastoplast was re-applied to the hand and wrist only.

By the 30th January there were no symptoms.

The patient returned to work after 14 days, but the Elastoplast wrist strapping was retained for a further week.

The details and illustration above are of an actual case. T. J. Smith & Nephew, Ltd., manufacturers of Elastoplast, are privileged to publish this instance, typical of many in which their products have been used with success in the belief that such authentic records will be of general interest.

In Elastoplast elastic adhesive bandages a combination of the particular adhesive spread with the remarkable STRETCH and REGAIN properties, together provide the correct degree of compression and grip. They mould readily to any part of the body without slipping, rucking, or constriction. Elastoplast bandages are available in widths of 2", 2½", 3" and 4" x 5/6 yds. long when stretched. Also 2" wide x 1½ yds. (stretched). Elastoplast, Elastocrepe, Jelonet and Gypsona are products of T. J. Smith & Nephew, Ltd., Hull, England.

Agent: RALPH PAXTON, 10, Lall Bazar, Calcutta

WOMEN AND THE CLIMACTERIC

For thousands of women who undertake heavy tasks through employment—and even in the home—muscular pains, backache and headache are the inevitable results of too-prolonged efforts.

This applies particularly to those subject to dysmenorrhoea and those approaching middle age and the climacteric.

Veganin gives most satisfactory results in such conditions since it is a synergistic association of codeine, acetylsalicylic acid and phenacetin, producing rapid and prolonged relief without ill effects. Veganin is not advertised to the public.

ACETARSOL VAGINAL COMPOUND

— BOOTS —

VAGINAL ANTISEPTIC

Acetarsol Vaginal Compound—Boots is a preparation containing acetarsol with boric acid and carbohydrate for local application in the treatment of leucorrhoea associated with *Trichomonas vaginalis*.

Clinical results have shown that Acetarsol Vaginal Compound—Boots is superior to vaginal douches, and the patient is spared much inconvenience on account of the ease with which treatment can be carried out.

Supplied in tablets each containing
4 gr. acetarsol.
Bottles of 25 and 100.

For particulars

please apply to

BOOTS PURE DRUG COMPANY (INDIA) LTD.

P.O. Box 2070
CALCUTTA

P.O. Box 680
BOMBAY

P.O. Box 158
Br. COCHIN

Manufactured by:

BOOTS PURE DRUG CO., LTD. NOTTINGHAM, ENGLAND

TABLE V (confirmatory)

Result with 2 c.c. of H_2O_2 solution after 48 hours

	Acidity	Peroxidase	H_2O_2
(1) Open bottle	16°	Nil	V. M. trace
(2) Closed bottle	21°	Nil	Nil
(3) Raw milk without H_2O_2 .	78°	Present	Nil

so will be ascertained in the subsequent investigation.

Summary and conclusion

The minimum dose of hydrogen peroxide solution to preserve the milk for 48 hours is found to be $2/5$ ths of an ounce or 16 grains of the solid compound per pint. The milk so treated

should be kept preferably in an open vessel. Vitamin A is not affected but vitamin C is somewhat reduced. The analytical constant, viz fat percentage, remains the same, while the lactose percentage is slightly reduced. The taste of milk is hardly altered by the small trace of H_2O_2 left behind which, however, disappears on boiling.

My thanks are due to the Director, All-India Institute of Hygiene and Public Health, and to the Director, School of Tropical Medicine, for their interest in the work.

The Use of Tantalum in Tendon Reconstruction of the Hand

By R. C. PEARLMAN

(Abstracted from the *United States Naval Medical Bulletin*, Vol. 46, November 1946, p. 1647)

In tendon reconstruction, active and passive motion are demanded within a few days following surgery to reduce the inevitableness of permanent immobility. To keep the swelling at a minimum the following criteria must be observed: (a) Traumatize the tissues as little as possible; (b) there must be no constrictive tissue; and (c) the proper application of a pressure dressing.

To permanently prevent adherence and obtain freely functioning tendon, the writer reports in this article his personal experience in the use of tantalum as an interpositional substance. Various metals and alloys have been buried in the tissues of the body by surgeons for the past 3 or 4 hundred years. For a metal or an alloy to be satisfactory in the presence of tissue fluids it must be 'inert' physically and chemically. After fulfilling this basic requirement, further physical characteristics of a metal or alloy should possess are: (1) its ductility, that it can be 'cold-rolled' and its ability to be tempered to various degrees of hardness. It was not until 1936 that a 'metal-like' material was produced that fulfilled any of these requirements. That was vitallium, an alloy of the following consistency: cobalt 65 per cent, chromium 30 per cent and molybdenum 5 per cent.

Vitallium possesses only one of the chemico-physical properties listed, 'inertness' in the presence of the body fluids. Screws, nails and plates of this alloy are in use, especially in bone work, but all have to be cast. It cannot be drawn into wire or shaped with a hammer at the operating table. Since the stainless steels vary so much in composition, they all, so far, irritate the tissues, and their use is limited almost entirely to sutures. At present, there is only one metal-like substance that possesses four of the necessary chemico-physical properties. It is tantalum.

Tantalum is a basic element discovered by Ekeberg of Sweden in 1802. It possesses the following properties: (1) Inertness, (2) malleability, (3) ductility, (4) it can be cold-rolled. It can be purchased as sutures, ribbon, foil, plates and screws. Laboratory studies show that there is no inflammatory reaction when tantalum is buried in the tissues. It appears totally inert. The tissues in contact show no tendency of disintegration and the tantalum appliance does not loosen or cause

a foreign-body reaction. It handles easily as suture material of various sizes but the writer would like to see a finer-sized suture and an increase in tensile strength. Tantalum plates, of varying thickness, are extensively used in neurosurgery, following bone losses of the skull, and the foil is used to prevent adherence between the cerebral and meningeal surfaces.

In the writer's reconstructive work he has been using tantalum foil 0.00025 inch in thickness as an interpositional material. It has improved the functional results of tendon work and often has made it unnecessary to resect a scarred and adherent tendon. Tendon with raw surfaces was simply encased within tantalum foil and the foil held in place with catgut ligatures. The tantalum-wrapped tendon was then dropped back into its normal channel. A pressure dressing was applied and the part immobilized for three or four days. At the end of that time active and passive motions were begun. The pressure dressings were reapplied and no splinting was necessary. The tantalum foil did not need to be removed. Examination of the tendon at the end of four to six weeks showed the tendon 'free' in its channel. The foil was found fragmented and closely adherent in part to adjacent tissues. The tendon itself was coated with a glistening layer of cells. The gauge of foil was not always available, and the writer then was forced to use heavier foil. The results with the heavy foil contra-indicate its use, as it slid about, often causing pressure necrosis of the skin, and in addition it had to be removed, making another operation necessary.

The writer feels that the results he has obtained with tantalum foil justify its continued use.

Penicillin in the Treatment of Louse-Borne Relapsing Fever

By H. S. INGRAHAM

and

R. G. LAPENTA

(Abstracted from the *United States Naval Medical Bulletin*, Vol. 46, November 1946, p. 1719)

1. FIFTY-two patients with Egyptian louse-borne relapsing fever received 1,000,000 units of penicillin each in 25,000 unit doses intramuscularly every 3 hours. A cure of the relapsing fever was obtained in all 52 cases.

2. No relapses occurred in the treated group.
3. Relapse occurred in 87 per cent of the 53 cases used as controls.

Leptospirosis Canicola A Case treated with Penicillin

By M. D. BABER
and

R. D. STUART

(Abstracted from the *Lancet*, ii, 26th October, 1946, p. 594)

A CASE of leptospirosis canicola in a boy is ascribed to bathing in the Thames.

The diagnosis was established by the demonstration of a rising serum antibody titre to *L. canicola* during the course of the illness and by absorption tests with homologous and heterologous strains of leptospira.

The patient was treated with 220,000 units of penicillin, and dramatic clinical improvement followed.

Experimental Gonorrhoea

(Abstracted from the *British Medical Journal*, ii, 12th October, 1946, p. 549)

CERTAIN facts which emerged may be recapitulated briefly. Cultured strains of gonococci failed to cause clinical disease with any consistency, and the older the strain the less likely it was to prove effective. The most successful method of conveying infection was by transferring pus from an acute case directly to the urethra of a volunteer, but even this method sometimes failed to infect. A heavy inoculum, deep insertion into the urethra, and the use of mucin or peptone solution rather than saline—which was shown to be toxic to the gonococcus—increased the chances of success. Patients infected with sulphonamide-resistant strains did not respond to sulphonamide therapy but were cured by penicillin. Those with a positive seemed less liable to infection than those with a negative complement-fixation test, and the same applied to volunteers with a previous history of gonorrhoea. The incubation period of experimental gonorrhoea averaged 3 to 5 days, with extremes of 1 and 31 days. When originally examined 1 per cent of the volunteers harboured typical gonococci without showing clinical signs, and were therefore carriers.

Cutaneous Anthrax

By H. V. ELLINGSON *et al.*

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 3rd August, 1946, p. 1105)

ALL patients in the present series (25) were treated with penicillin in total dosages ranging from approximately 1,000,000 units to over 4,000,000 units. Since the first 3 cases occurred at a time when, to our knowledge, penicillin had not had clinical trial in this infection, these three individuals also received sulphadiazine orally in doses sufficient to maintain blood levels above 8 mg. per hundred cubic centimetres for from four to eighteen days. In the remaining patients penicillin was used alone. In general, the plan of therapy was to give 60,000 units intramuscularly in each of five doses, followed by 30,000 units every three hours by the same route. Deviations from the standard programme occurred in several cases when larger doses were given and in 2 cases when penicillin was administered by continuous intramuscular infusion for brief periods. In most cases dressings applied to the lesions were kept moist with penicillin in saline solution (1,000 units per cubic centimetre) for seven days. In general, intramuscular penicillin therapy was continued until the following criteria were met: (1) Oedema

had begun to recede, (2) cultures from lesions were negative for *B. anthracis*, (3) systemic symptoms had subsided, and (4) lesions were drying. Blood penicillin levels were not determined. No other treatment was given other than acetyl-salicylic acid for symptomatic relief and general supportive measures. All patients were kept at bed rest during the acute phase of their infections and, when possible, affected parts were immobilized.

All recovered uneventfully in spite of the fact that *B. anthracis* was isolated from the blood stream of 3 of these patients prior to treatment. Under treatment, 14 of the patients showed only slight systemic reaction or none at all. Furthermore, the disappearance of viable anthrax bacilli from the lesions in twenty-four hours or less in 22 of these cases is considered significant.

The Use of Para-Aminobenzoic Acid in Endemic (Murine) Typhus

By P. K. SMITH

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 3rd August, 1946, p. 1114)

1. A SERIES of 29 patients with endemic (murine) typhus were given 2 gm. of para-aminobenzoic acid every two hours until their temperatures returned to normal.

2. The number of days of fever in patients receiving this treatment was, on the average, significantly less than in a comparable series of patients not receiving the drug.

3. No toxic effects that could be attributed to para-aminobenzoic acid were observed in a group of 46 patients, each of whom received an average of 95 gm. of the drug. Twenty-nine of these patients had murine typhus.

4. It is recommended that a thorough clinical trial be made of this drug, using a larger number of patients under more rigidly controlled conditions. Such trials should include appropriate studies designed to detect any early toxic effects.

Boric Acid as a Stomach Poison for the German Cockroach

By O. S. BARE

(From the *Journal of Economic Entomology*, Vol. 38, 1945, p. 407, as abstracted in the *Review of Applied Entomology*, Vol. 34, Series B, October 1946, p. 167)

BAITS composed of 10 per cent powdered boric acid with a mixture of equal parts of honey and butter and with powdered confectioners' sugar gave 80 per cent kill in 9 and 13 days and complete kill in 16 and 21 days, respectively. Nymphs that hatched in the jars containing these baits died in the first instar, whereas those that hatched in control jars developed normally. Both baits were eaten readily even in the presence of common foods, and would be particularly suitable for use where quicker acting and more violent poisons might be dangerous.

The Modern View of Gold Treatment in Rheumatoid Arthritis

By G. D. KERSLEY

(Abstracted from the *Medical Press and Circular*, Vol. 216, 23rd October, 1946, p. 296)

SEVERE reactions are rare if one of the less toxic crystalloids are used in small dosage of not more than 50 mg. at a time, and if they are given intramuscularly at weekly intervals to a total of not more than 1.0 gm. per course. In only about 12 per cent of cases will it be necessary to cut short the course, the commonest

cause of annoyance being a dermatitis, which is only occasionally severe. In such cases the patient has the consolation that he is almost invariably cured, at least for a time, of his arthritic symptoms. Since the introduction of penicillin the fear of the consequences of agranulocytosis has disappeared, since it is infection, not the drop in the polymorphonuclear cells themselves, that kills. Thrombocytopenia is, however, still a dangerous but moderately rare result of gold treatment, though the use of vitamin K may assist in reducing its terrors. A moderate degree of albuminuria without red cells in the urine is not an indication for cessation of treatment.

With regard to the preparation of gold to be used, either myocrisin (sodium aurothiomalate) or auro-calcium (calcium aurithiomalate) are those most frequently employed in this country, the calcium salt being probably slightly less toxic. Calcium should be also administered by injection at the same time if the sodium salt is used.

Dosage must, of course, be regulated according to the patient's reactions, increase in pain in the joints, albuminuria, or slight fever being an indication that the dosage should not be increased. If, however, there are no complications the following course may be followed:

0.01 gm. \times 3 doses; 0.025 gm. \times 3 doses; 0.05 gm. \times 18 doses. Total—1.0 gm.

Within about a month there is frequently some diminution of pain and swelling, and perhaps an increase in sense of well-being and appetite. If there is any such improvement the course should be repeated in six to twelve weeks. If there is neither clinical improvement nor drop in the sedimentation rate, it is unusual to obtain any benefit from a second course.

In conclusion, it is fair to state that any case of rheumatoid arthritis, who has a rapid sedimentation rate, who is not definitely improving after a month or so of rest, both mental and physical, coupled with good food, analgesics and elimination of definite sepsis, should be given the benefit of gold therapy. If, during the course, a watch is kept on the skin and the urine and periodic platelet and white counts are done, then the risk of severe toxic symptoms is slight and is far outweighed by the likely therapeutic advantages.

B.C.G. : The Present Position in Britain

(Abstracted from the *Pharmaceutical Journal*, Vol. 157, 5th October, 1946, p. 216)

B.C.G. VACCINE consists of a suspension of living B.C.G., and its efficacy depends upon the number of living organisms contained in the suspension at the time of vaccination. But their life is short; too short to enable tests for sterility to be made before use, or to ensure that no virulent tubercle bacilli are present. The only way in which the purity of the vaccine may be ensured is by having it cultured and prepared under the strictest aseptic precautions in a special laboratory by a tuberculosis-free staff wearing masks during certain of the operations and preferably employed upon no other bacteriological work. The fulfilment of these requirements is costly, and special measures will undoubtedly be necessary to finance the production in this country of B.C.G., especially in the early stages when only limited quantities can be produced. It is proposed, therefore, to arrange for the production of the vaccine in this country under the auspices of the Ministry of Health.

So far B.C.G. vaccination has not shown such immunizing power as to make it a substitute for any of the existing methods of control and treatment. These are still essential and B.C.G. can be regarded only as a promising addition to existing measures. It is possible that, in time, avirulent strains of other bacilli of the tuberculosis group may be proved to have even greater immunizing power than B.C.G. The vole bacillus (*Mycobacterium tuberculosis muris*) is at present the only one whose potentialities in that direction look at all promising.

Pulex irritans

By B. DE MEILLON

and

D. H. S. DAVIS

(Abstracted from a correspondence in *Trans. Roy. Soc. Trop. Med. Hyg.*, Vol. 39, No. 6, June 1946, p. 544)

Pulex irritans, the human flea, has been shown to be capable of transmitting plague. MacArthur recently drew attention to its adaptation to a host other than man. This has a considerable bearing on the epidemiology of this disease. De Meillon now points out that from the flea survey in the Union of South Africa it has become apparent that this flea is not so restricted in its choice of host as is generally believed. It was found not only on the house rat but was collected also from different animals including domestic dog, domestic pig and domestic calf.

D. R.

Venomous Marine Molluscs of the Genus *Conus*

By L. C. D. HERMITTE, M.B., Ch.B., D.T.M. & H.

(Abstracted from *Trans. Roy. Soc. Trop. Med. Hyg.*, Vol. 39, No. 6, June 1946, p. 485)

THE fact that certain fishes can inflict either poisonous bites with their teeth or venomous stings by means of spines situated in their fins or in their opercula has been fully recognized. There are also fishes which are poisonous when eaten. The author has now discovered that certain marine molluscs belonging to the family Conidae and genus *Conus* may be responsible for serious and even fatal consequences to human beings. The accidents occur at the time of handling them when a sharp 'sting' is felt on the palm. These Gastropods are peculiar in possessing a special gland opening into the middle of the oesophagus known as the 'gland of Leiblin'. It has an irritating secretion which may be regarded as poisonous. A bite from such an animal is fatal only in exceptional cases; it often causes severe illness. The different species of *Conus* which can inflict such bites are *C. geographus* Linn. and *C. leopardus* Linn.; these inhabit the tropical island lagoons.

D. R.

A Case of Recovery of a Biliary Pulmonary Fistula

By A. SHEDROW

(Abstracted from the *South African Medical Journal*, Vol. 20, 10th August, 1946, p. 446)

THE patient, a male, 65 years of age, with no relevant past history except chronic bronchitis and cough, took suddenly ill, with acute pains in the right hypochondriac region. On examination, it was found that he had initial signs of dry pleurisy and later of basal pneumonitis on the right side. Sulphadiazine followed by penicillin treatment had no effect. Thereafter, the patient began to expectorate copiously, and the sputum did not suggest any extra-pulmonary condition. He was now in his third week. Laboratory examination of the stools were made for amœbæ, but the result was negative. At a certain stage the sputum looked slightly hæmorrhagic and thick, and suggested a possible lung carcinoma. An x-ray taken at the bedside did not suggest any malignant growth. At the fourth week a new and dramatic sign appeared. The patient complained that when he expectorated he had a very bitter taste in his mouth; the sputum changed its colour and consistency, and became distinctly yellow and most copious. Examination of the sputum revealed the presence of bile. He was put immediately on

emetine, and within seven days made a miraculous recovery.

The case was diagnosed as amœbic abscess of the liver which burst through to the bronchi and formed a hepato-pulmonary fistula through which the abscess drained. It is concluded that a possibility of liver abscess should be mentioned when a case with right-sided basal signs does not respond to chemotherapy even if laboratory findings are negative.

Diaphragmatic Flutter, with Symptoms Suggesting Angina Pectoris

By E. F. CAIN

and

E. R. WARE

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 27th July, 1946, p. 1058)

At 1 a.m. on 1st September, 1944, an elderly man was brought by ambulance to the writers' hospital. Information available at that time was that he had collapsed on one of the Oakland streets a few moments after alighting from a bus. He was brought to a civilian hospital where he stated that he was a recently discharged army officer. Because of this statement, communication with this hospital was made and he was quickly transferred here. When seen by the officer of the day, he complained of severe excruciating pain in the lower part of his left chest, associated with extreme dyspnoea, his statement being 'It seems as if my heart were only half working; can't get my breath'.

General physical examination showed that the patient was thin and moderately emaciated. Respiratory movements were shallow and restricted, owing, he said, to aggravation of his pain on inspiration. Two healed depressed scars were readily seen on each side of his neck. These, he stated, represented stab wounds inflicted by a Jap during the recent Tarawa invasion. A tattooed wreath of flowers was seen on his left arm 1½ inches above the wrist, and on the right arm a tattooed American eagle was found. The pulse at the wrist was 60. The heart rate at the apex was apparently extremely rapid and was variously estimated at 280 to 300 beats per minute. No abnormalities were found on clinical examination of the chest or abdomen. The peripheral tendon reflexes were normal. The pupils reacted normally. Some atrophy of the left half of the tongue was noted. Because of the apparent discrepancy between the pulse rate at the wrist and at the heart apex, a tentative diagnosis of auricular fibrillation was made; and because of his obvious pain and dyspnoea, morphine was considered necessary and he was placed in an oxygen tent. A bedside electrocardiogram was taken and showed an essentially normal tracing. A portable roentgenogram of the chest showed only elevation of the left half of the diaphragm, with displacement of the heart and aorta to the right.

The obvious incongruity of the findings gave rise to some informal discussion. Lieut. Sam Zlotnick, M.C., hearing this, was immediately impressed with the resemblance of the clinical picture to that presented by a patient whom he had seen in 1942 in a civilian hospital in Ohio and, remembering the scars on the man's face, he became convinced of his identity. After seeing the patient, Lieut. Zlotnick recalled the reports of hospitalizations on this person, and the exact determination of the patient's identity developed from a perusal of these and other records.

His course in the hospital was characterized by recurrences of chest pain and dyspnoea. Each episode developed spontaneously and apparently terminated in the same way. During the recurrences a fluoroscopic examination of the chest showed a flutter of the right portion of the diaphragm. Little or no motion of the left side could be detected.

Routine blood counts showed 3,580,000 erythrocytes and 7,700 leukocytes per cubic millimetre. The hæmoglobin was 73 per cent. The differential count showed

49 per cent neutrophils, 48 per cent lymphocytes, 2 per cent monocytes and 1 per cent eosinophils. The sedimentation rate was 31 mm. in one hour. A blood Kahn reaction was reported 'doubtful' on two occasions, but the blood Wassermann reaction was negative.

There are several points of interest in regard to this man's identity and unreliable accounts of his past history and occupations. He can be readily identified by the scars and tattoo marks. He has been registered under a number of different names and has claimed to have been a deep sea diver, a miner, a trapper, a Texas deputy sheriff and a retired regular army officer with extensive tropical service, terminating in this last war, where he states he was wounded in the neck in combat with the Japanese.

Besides the hospitalizations mentioned in the previous descriptions of this case we have ascertained that the man has been hospitalized in Weimar Sanitarium, Colfax, Calif., the Veterans Administration Facility, Livermore, Calif., the Dibble General Hospital, Menlo Park, Calif., and Highland-Alameda County Hospital.

It seems pertinent to publish additional information in regard to the further interesting course of this man.

Infectious Lymphocytosis in Brothers

By M. LORENZ *et al.*

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 13th July, 1946, p. 882)

Two boys presented the typical picture of acute infectious lymphocytosis as described in the literature. The salient features of the disease were the benign clinical course and the distinct leukocytosis with a high percentage of mature lymphocytes. The parallel onset and course speak highly in favour of a specific infectious agent as the cause.

In some of the earlier reports cases simulating infectious lymphocytosis were described as infectious mononucleosis. However, close analysis reveals consistent differences between the two conditions. The most striking difference is the decided increase in normal small lymphocytes in infectious lymphocytosis as compared to the slight or moderate increase in atypical lymphocytes in infectious mononucleosis. Further, the heterophil antibodies are not significantly increased in infectious lymphocytosis.

Our patients presented features not previously described in the literature that might be considered to favour a relationship to infectious mononucleosis. One of the boys had a palpable spleen; with the pronounced lymphocytosis, it is remarkable that this does not occur more commonly. The bone marrow hyperplasia found in both boys has also been noted in infectious mononucleosis. The presence of heterophil antibodies in a dilution of 1 : 80 has not been described by other authors. However, the fact that such titres occur in a variety of infections in children vitiates the significance of this mild reaction. The few atypical lymphocytes that appeared at the end of the disease may be considered to be a non-specific type. We feel that these features observed in infectious lymphocytosis are not sufficiently striking to identify the disease with infectious mononucleosis.

It might be further questioned whether infectious lymphocytosis is a variety of whooping cough. When first seen, both of our patients had a mild cough associated with a respiratory infection. There were no paroxysms, and the cough subsided in about a week, at which time the lymphocytosis was at its peak. In whooping cough the maximum lymphocyte count is usually reached in the paroxysmal stage about the second to the fourth week.

Reports of cases of infectious lymphocytosis have coincided roughly with the use of pertussis vaccine. Since our patients had previously received this vaccine, we considered the possibility of a subclinical type of whooping cough with a typical blood picture but without the usual cough or clinical course. Sauer has never observed such a picture in a large series of children who received pertussis vaccine.

From the data available, it appears that infectious lymphocytosis is a separate disease entity rather than an atypical type of infectious mononucleosis or whooping cough.

Sulphathiazole and Penicillin in Typhoid Fever

By C. J. McSWEENEY

(Abstracted from the *Lancet*, ii, 27th July, 1946, p. 114)

FIVE cases of severe typhoid were treated with sulphathiazole and penicillin.

The first case was given doses of penicillin appropriate for a staphylococcal infection, with no appreciable effect on the pyrexia or blood cultures, although toxæmia was much lessened, and there were no complications due to ulceration.

The next four cases were treated intensively with penicillin and sulphathiazole, receiving two courses each comprising 10,000,000 units of penicillin and about 34 g. of sulphathiazole given in four days. Speedy disappearance of toxæmia, subsidence of pyrexia, and disappearance of organisms from the blood, fæces, and urine followed the end of the second course in three of the four cases. In the fourth case, when the second course was postponed for about a fortnight, there was a relapse, which rapidly subsided when the second course was initiated.

The clinical effects appear to confirm the laboratory findings of Bigger.

POSTSCRIPT

Since this paper was submitted for publication another severe case of typhoid fever has been treated with penicillin and sulphonamides as follows:—

Case 6.—A girl, aged 17 years, admitted on 16th March, 1946, in the 3rd week of her typhoid, gravely ill, bordering on 'typhoid state'. Clinically enteric—abdomen very distended, spleen palpable, rose spots present, temperature 102°F–103°F, pulse rate 122–140, respirations 30–36 per min., Widal positive for *Bact. typhosum* 'H' to 1/250 and for 'O' to 1/50.

Because of the patient's grave condition it was decided to start penicillin-sulphonamide treatment before the result of the blood culture was available, and, accordingly, the system of treatment followed in the last 4 cases of the series described above was initiated on 18th March. The first course was finished on the 21st; the second began on the 24th and terminated on the 28th. After the conclusion of the second course the temperature, which had ranged between 100°F. and 104°F. while the treatment was being applied, underwent lysis and has been settled since 6th April. Toxæmia was much lessened from the time the treatment was started and was absent before the second course was concluded. The blood cultures taken on the conclusion of the second course were negative and ten samples each of fæces and urine examined during and subsequent to the treatment were negative for *Bact. typhosum*. No ulcerative accidents of any kind occurred, and the patient's condition gave rise to no anxiety after the conclusion of the second course of treatment.

There appears to be a strong *prima facie* case for extending this new line of treatment to the typhoid carrier state, and investigations along these lines are in progress in Eire.

Scorpion Sting

(From the *British Medical Journal*, ii, 2nd November, 1946, p. 680)

DR. B. V. RAMASWAMY (Bangalore, South India) writes: In the *Indian Medical Gazette* of November 1939, and January 1940, there were two small notes about scorpion sting. (i) 'Fresh leaves of *Acalypha indica* when rubbed well at the site of the sting relieve the pain and cure the patient in about five minutes.'

(ii) 'A few whiffs of chloroform inhalation almost immediately cure the pain. About 2 dr. (7 ml.) may suffice for nearly 50 persons.' Since then I have tried chloroform inhalations for scorpion stings with great success. There are two types of pain experienced by such patients. One is a local, throbbing pain at the site of the sting, and the other a rapidly spreading, shooting pain. If the patient gets the treatment within 5–10 minutes of the sting both the pains disappear in about 5 minutes. In cases where the treatment is begun after some time—more than half an hour after the sting—the shooting pain disappears in 5 minutes, but the local pain persists though in a bearable degree. To eliminate that pain I usually inject a local anæsthetic all round the site of the sting which gives complete relief. *Treatment*.—A few drops of anæsthetic chloroform are sprinkled over a small piece of cotton-wool and held near the patient's nostrils. He is then asked to inhale deeply a number of times. Most of the patients if treated early find relief of pain in 2–5 minutes. I would very much like others to try this simple treatment and report their experience. I would also like to know how chloroform neutralizes the toxins of the scorpion.

Agranulocytosis Induced by Aminopyrine Suppositories

By E. URBACH

and

H. L. GOLDBURGH

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 13th July, 1946, p. 893)

AN attack of nearly fatal agranulocytosis followed the use of twenty-four rectal suppositories of aminopyrine over a period of nine days amounting to 6.5 gm. (103 grains). Recovery was brought about by the administration of 1,275,000 units of penicillin given over a period of six days.

Memorandum on B.C.G.

(Abstracted from the *Lancet*, ii, 27th July, 1946, p. 138)

THE bodies sponsoring the memorandum ask that the use of B.C.G. should be encouraged, but feel strongly that its employment should not be allowed to discourage the search for more efficient means.

When Calmette advocated the administration of B.C.G. to newborn infants, he believed that it would provide sufficient protection to prevent a natural infection during the first year or two of life, and that sufficient resistance would remain to enable later infections to be overcome and to leave in their turn the higher grade of immunity associated with such recovery. This sequence represents perhaps the most effective result which any form of artificial immunization can produce. B.C.G. vaccination was advocated especially for children exposed to special risks, and it has been among these that the most successful results have been claimed in France.

Another application of preventive inoculation is the immunization of adolescents and young adults who are non-reactors to tuberculin. The value of pursuing this aspect has been shown in the vaccination of young nurses in Norway, where immunization of non-reactors has been followed by a significant decrease in morbidity and mortality rates as compared with unimmunized non-reactors, though both rates remain higher in the vaccinated than among the naturally infected reactors. The need for vaccination of this group in Great Britain is shown by the reports of the Prophit Trust investigations. The suggestion is that it should be available, though not compulsory, for non-reactor nurses. This would provide not only a practical safeguard against tuberculosis but a controlled investigation of the first value; there is little doubt that the results would be substantially the same as those obtained in Norway.

The introduction of the transcutaneous method, with its elimination of local abscesses, is felt to be an advance of the first importance; up to 1944 Birkhaug vaccinated 1,500 persons with a spring-actuated puncture instrument; 98 per cent became reactors and abscesses developed in none. There appears now to be no reason why B.C.G. vaccination should cause greater inconvenience, or rouse greater prejudice, than does prophylactic immunization against diphtheria.

It is believed that :

1. The harmlessness of B.C.G. is established beyond doubt.
2. A very considerable degree of immunizing efficiency is indicated by the most reliable results from other countries.
3. There exists in tuberculosis services and among the medical profession generally a desire that a reliable supply of B.C.G. vaccine should be available here, as it has been for years in other countries of the world.
4. The application by multiple puncture or by scarification promises to remove the risk of local abscesses, which has been one of the most serious obstacles to the general use of B.C.G.

On these grounds it is requested that the supply and use of B.C.G. vaccine in Great Britain should be facilitated and encouraged.

In the production of B.C.G. for general use it appears to be essential that: (1) the material should be actually safe; (2) there should be public confidence in its safety; and (3) control of production should be such that any claim of tuberculous disease being due to vaccination should be refutable with certainty. It is believed that, to attain these objects, there should be a single source of supply for Great Britain and that commercial competition should be avoided. It is also felt that the product should be supported with official backing, by being prepared under the auspices of a Government department or the Medical Research Council, or by certification of the methods employed which should be provided by an official department, such as the standards department of the Medical Research Council. Failing manufacture under Government auspices, it is felt that production should be controlled by some scientific organization of national repute, which should be subjected to official supervision and certification. Considering that in Norway, during enemy occupation, the number of vaccinations was increased from 603 in 1939 to 17,579 in 1944, it does not seem impossible that an adequate and reliable supply should be forthcoming in Great Britain.

The Syndrome known as 'Reiter's Disease'

By W. P. U. JACKSON

(Abstracted from the *British Medical Journal*, ii, 10th August, 1946, p. 197)

CLINICAL MANIFESTATIONS

The patient is usually a young adult male, presenting with an irregular fever and any one or more of the triad of essential symptoms. If one (e.g. the arthritis) occurs alone at first, the others (i.e. urethritis and conjunctivitis) develop later. The conjunctivitis is bilateral, catarrhal, or, more usually, profusely purulent, with episcleritis and sometimes an iritis or keratitis. There are local pain, weeping and photophobia, but permanent damage to the eye does not occur. No constant organism can be found in conjunctival smears. The arthritis is manifested by severe pain and tenderness, occurs in the large joints of the limbs, is usually polyarthritic and often fitting. Synovitis is frequent, fluid developing rapidly and in considerable amount. This fluid may be purulent, but is always sterile. The urethral discharge is abundant and purulent, accompanied by surprisingly little frequency of, or pain on, micturition. Gross hæmaturia may occur and renal complications have been described. The urine contains red blood cells in varying numbers,

clumps of pus cells, and a little albumin. The discharge presents no evident organism and is sterile on attempted culture. Erosions and small ulcers may appear on the penis from the constant irritating discharge.

Diarrhoea, sometimes severe and bloody, may be present at the onset, and several types of more or less generalized rashes have been described. The erythrocyte sedimentation rate is raised, there may be a mild hypochromic anaemia, and the leucocytes are normal or slightly raised in number. Gonococcal fixation and Wassermann tests are negative. The disease is self-limited, though subject to recurrences, which may drag its course out into months. Complications are very rare.

ÆTIOLOGY AND DIFFERENTIAL DIAGNOSIS

Harkness claims to have demonstrated inclusion bodies in the discharge from the urethra and conjunctiva in five cases of Reiter's disease. Apart from this all efforts to discover an infecting agent have failed, although the hypothesis of virus causation is the most popular. One thing seems certain—this is no venereal disease, and bears no relation to gonorrhoea or syphilis.

TREATMENT

Miller and McIntyre consider that putting the patient to bed for six weeks to three months is all that can be done. They found penicillin and sulphonamides to have no effect on their two cases. Protein shock therapy has been used in Germany, apparently with some success, especially by Beiglboeck. Sulphadiazine, however, seemed to have a good effect in a few cases.

CONCLUSION

The main importance of an awareness of the syndrome lies in its distinction from chronic gonorrhoea, thereby altering the prognosis and avoiding hectic treatment and the venereal stigma. It is probable, that Reiter's disease occurs much more commonly than is recognized, but it is considered that the symptom-complex described above is pathognomonic and should usually be unmistakable.

A Rare Iso-Hæmagglutinin

By J. J. GRAYDON

(Abstracted from the *Medical Journal of Australia*, Vol. II, No. 1, 6th July, 1946, p. 9)

OCCASIONALLY reports have appeared of unusual or irregular iso-hæmagglutinins which have been found in the blood of certain subjects and have occurred independently of the A,B,O, the M,N, and the Rh blood types. Most of these factors have been detected by means of 'cold' agglutinins, which are seldom active above a temperature of 30°C.

The serum of one donor (L. J.), who was of blood group O, had a titre of 1/250 for group A1 cells, 1/120 for group A2 cells, greater than 1/500 for group A2B cells, and 1/120 for group B cells in tests performed at 37°C. However this group O serum unexpectedly agglutinated cells G, also of group O, to a titre of 1/32 at 18°C. and 1/4 at 37°C.

Sixty-one samples of group O cells were not agglutinated by this serum. As Rh-positive, Rh-negative, P-positive and P-negative cells and all of the M,N types were well represented in this series, the 'new' antigen was probably unrelated to the Rh and M,N systems and the P-factor.

L. J. serum was used against samples of group O cells obtained from 91 Papuans and 39 Australian aborigines. None of these was agglutinated by L. J. serum. The specific antigen detected by the 'atypical' agglutinin in L. J. serum is evidently rare. The antigen, which had been given the tentative designation 'Gr', to distinguish it from the 'G' factor of Schiff, has appeared in three successive generations of G family, but so far has not been found in any subjects who are not close relatives of G. Hence it is apparently inherited as a

Mendelian dominant character unrelated to the A,B,O and the M,N blood types. Its rareness in the white population indicates that it is not related to the P factor or to the 'Lutheran' antigens.

It may be identical with the 'Levy' antigen, but the rareness of both makes this unlikely. Further, the 'Gr' agglutinin was more active in the cold than at 37°C., where the 'Lutheran', 'Willis' and 'Levy' antibodies were more active at 37°C. than at lower temperatures. It is worthy of note that the 'Gr' agglutinin could be absorbed with G cells to leave a normal group O serum of high titre. Also it was found possible to absorb the anti-A1, anti-A2 and anti-B agglutinins from the original serum, leaving a fluid which could be used to detect the 'Gr' antigen in cells of any group.

The donor (L. J.) was an unmarried girl, aged eighteen years, with a clear medical history. She had never had a blood transfusion, and no reason for the development of the unusual agglutinin could be found.

The specific agglutinins are preserved by freeze-drying samples of the serum in ampoules.

Application of the Rh Blood Types and Hr Factor in Disputed Parentage

By ALEXANDER S. WIENER, M.D.

(Abstracted from the *Journal of Laboratory and Clinical Medicine*, Vol. 31, No. 5, May 1946, p. 575)

THE proper application of the rules of inheritance of Rh and Hr requires considerable genetic and serologic knowledge and lawyers, in particular, have requested detailed tables listing all the possible matings for reference use. The tables are far more elaborate than in the case of the blood groups and M-N types, and some of the matings involve rare types which will hardly ever be encountered in practical work. Nevertheless, in view of the need for such a complete set of tables, this paper was prepared.

Blood not agglutinable by any of the three Rh antisera is said to be Rh negative, or, more simply, is said to belong to type rh. Types Rh', Rh'', RhRh'', and rh₀ are named after the antisera with which these bloods react. Type Rh₁ reacts with the two anti-scr_a, anti-Rh' and anti-Rh₀, and Rh₁ is merely an abbreviation for Rh₁'; similarly, Rh₂ is short for Rh₂'. Types Rh₁ and Rh₂ are so named, instead of RhRh' and RhRh'', respectively, to indicate that the two factors Rh₁ and Rh₂ in the former, and the factors Rh₀ and Rh'' in the latter behave like 'partial' antigens in complex agglutinogens which are, as a rule, hereditarily transmitted as units by the corresponding genes, R' and R''. Type rh₀ is printed with a small 'r' to indicate that this type bears a similar relation to types Rh₁, Rh₂, and RhRh₁, to that which type rh bears to Rh', Rh'', and RhRh''. In giving the names of the Rh types verbally, however, it is not necessary to say small 'r' or large 'r', as the case may be, because the qualifying subscripts and superscripts will prevent any ambiguity.

According to the theory of six allelic genes, the eight Rh blood types are hereditarily transmitted by means of a series of allelic genes, r, R', R'', r⁰, R¹, and R².

When the 8 Rh blood types are applied in cases of disputed parentage, the practical consequences of the theory of six allelic genes can be summarized in the following two rules: (1) The factors Rh₁, Rh', and Rh'' cannot appear in the blood of a child unless present in the blood of one or both parents. (2) When either parent belongs to type RhRh₁ or RhRh'', no child of type rh or rh₀ can occur. Similarly, parents of type rh or rh₀ cannot have children of type RhRh₁ or RhRh''.

In studies of the eight Rh blood types on a total of 300 families with 620 children, the writer has not encountered a single exception to these two rules of heredity.

However, that rare but valid exceptions to the second rule of heredity may eventually be encountered follows from the discovery of the rare Rh₃ gene by Murray,

Race, and Taylor and of the so-called intermediate genes.

The standard Hr factor occurs as a partial antigen in the agglutinogens determined by genes, r, r⁰, R', and R'' and is absent from the agglutinogens determined by genes R' and R'' (and R¹ and R²).

The designations of the sub-types were selected to indicate the most common genotype occurring among individuals of each subtype in question.

The results that can be drawn from the two laws of heredity when applying the Hr-Rh tests in cases of disputed parentage are presented in a table. By increasing the number of identifiable Rh blood types from eight to ten, the use of anti-Hr serum has considerably increased the number of possible matings.

The Absorption, Excretion and Toxicity of Streptomycin in Man

By D. G. ANDERSON

and

MARJORIE JEWELL

(Abstracted from *Bulletin of Hygiene*, Vol. 21, No. 5, May 1946, p. 329)

THE treatment of three patients with streptomycin is described, two were infected with *Salm. typhi*, a Group B Salmonella (blood culture positive in both), and one *H. influenzae* causing a meningitis. The response appears to have been decisive and rapid in the last named, but inconclusive.

Blood levels of streptomycin were determined after administration by different routes. There was no absorption when 6,000,000 units were swallowed probably due simply to non-absorption, since gastric juice was found not to inactivate streptomycin *in vitro*. When a single dose of 200,000 units was administered intravenously, a detectable blood level persisted for 8 hours: the curve following intramuscular injection was similar but for the absence of the immediate rise to a high level. Streptomycin is thus excreted or destroyed less rapidly than penicillin, and 6 or 8 hour intervals between doses are recommended. Examination of the urine showed that from 46 to 87 per cent of a single dose is excreted within 24 hours. There is little diffusion into the cerebrospinal fluid, but intrathecal injection of solutions containing 5,000 units per c.c. is apparently harmless and maintains a therapeutic level for 24 hours. Single intravenous injections caused transient headache and other unpleasant sensations and intramuscular injection caused pain; continuous intravenous administration is advised for prolonged treatment.

Permeability of the Human Placenta to Isoantibodies

By ALEXANDER S. WIENER, M.D.

and

EVE B. SONN

(Abstracted from the *Journal of Laboratory and Clinical Medicine*, Vol. 31, September 1946, p. 1020)

Two cases of erythroblastosis due to A and B sensitization are described.

Comparative titrations of the alpha and beta antibodies in the sera from cases 1 and 2 were carried out by the agglutination and conglutination techniques.

In the titrations carried out by the agglutination technique, it was found that the ratio of the antibody titres of the maternal and infants' sera was 8 : 1 in Case 1 and 64 : 1 in Case 2.

On the other hand, in tests carried out by the conglutination technique, the ratios of the titres approximated unity. The reason for the discrepancy

is that the two tests measure two different sorts of antibodies. The former test detects bivalent antibodies (agglutinins), while the latter test also detects univalent antibodies (glutinins). These results demonstrate, therefore, that glutinins traverse the placenta far more readily than agglutinins, in accordance with the expectations under the hypothesis that the former are comprised of smaller molecules.

It may seem somewhat puzzling that in both cases the univalent beta antibodies were more readily demonstrable in the maternal serum by the conglutination method than were the univalent alpha antibodies. The following plausible explanation for this apparent paradox suggests itself. It would be expected that univalent antibodies in general would continue to pass through the placenta from mother to fetus until their concentration in the fetal circulation became equal to that in the maternal circulation, thus setting up an equilibrium. In the case of the beta antibodies, such an equilibrium could be reached quickly; but in the case of the alpha antibodies, the antibodies would be neutralized or absorbed by group substances in the Group A fetus' body, delaying the attainment of equilibrium and at the same time gradually depleting the mother's body of the alpha antibodies.

The fact that in both cases described in this paper first-born infants were erythroblastotic calls for some comment.

In the first case, the patient stated that two years previously she had had an ovarian tumor removed and was given several post-operative transfusions of commercial, pooled human plasma.

With regard to the second case, the source of the sensitization could not be traced as definitely. However, it should be pointed out that A-like and B-like antigens are ubiquitous in nature, so that there would be many opportunities for A-B sensitization to occur in the course of a lifetime. For example, such antigens are present in horse serum and pig pepsin, so that injections of therapeutic horse serum or diphtheria toxin-antitoxin could bring about A-B sensitization. Moreover, such antigens are present in many bacteria and animal parasites, so that certain infections could cause A-B sensitization. The second patient did give a history of a severe attack of pneumonia several years before her first pregnancy, and possibly this was the source of her sensitization.

Guinea-worm

By T. S. SHASTRY

LIEUTENANT-COLONEL, I.M.S.

(Abstracted from *Journal of the Indian Medical Association*, Vol. XV, August 1946, p. 362)

DRACONTIASIS occurs in various parts of India where draught and water scarcity are present and where steep wells, ponds and pools are the sources of drinking water. The infestation causes pain and swellings in various parts of the body, specially the lower limbs and the joints therein, and the common sequelæ are arthritis, synovitis, ankylosis and contractures. For treatment of guinea-worm infestation the author recommends intravenous injections of 1 c.c. of 2 per cent aqueous solution of sodium antimonium tartrate every alternate day on an average of 3 injections, the usual precautions being taken. He submits records of 5 cases treated by him in this way with satisfactory results. As a prophylaxis he suggests a similar course of treatment for every new recruit who comes from an endemic area.

N. V. B.

Relationship of Benign Lymphocytic Meningitis and Glandular Fever

By H. TIDY

(Abstracted from the *Lancet*, ii, 7th December, 1946, p. 819)

THE clinical symptoms, course and prognosis of benign lymphocytic meningitis and of the neurological manifestations of glandular fever are indistinguishable.

The changes in the C.S.F. are identical in the two conditions.

In glandular fever with neurological manifestations the glandular enlargement is usually slight. This feature, together with mononucleosis and heterophil agglutinins, may only develop after the neurological symptoms have subsided, or may precede the nervous stage.

With the presence of such neurological symptoms, glandular fever can only be excluded by specific and repeated examinations.

Such examinations do not appear to have been performed in general in cases recorded as benign lymphocytic meningitis, and the possibility of glandular fever as a causal factor has consequently not been excluded.

Acute Infectious Mononucleosis complicated by Encephalomyelitis

By S. GELIEBTER

(Abstracted from the *Lancet*, ii, 23rd November, 1946, p. 753)

THIS case appears to be one of glandular fever in which the central nervous system was severely affected, followed by complete recovery. The Paul-Bunnell test was strongly positive (1-256) at the height of the nervous affection and became barely positive when the neurological signs had practically gone. Of particular interest is the fact that during the whole course of the disease there was a persistent leucopenia. At no time were the white cells more than 5,500; the lowest figure was 3,400. The mononuclears were never more than 7 per cent, the maximal lymphocytosis was 82.5 per cent. Tidy writes: 'It is evident that the virus of glandular fever transiently affects all the blood-forming tissues—and no single blood picture is typical of the disease.'

The C.S.F. never contained more than 9 lymphocytes per c.mm., even when the protein was 400 mg. per 100 c.cm. One might perhaps deduce that the small increase of white cells in the C.S.F. (and the consequent cell-protein dissociation) was ætiologically related to the leucopenia. This relationship, however, has still to be proved, just as much as the reputed relationship between the increase of leucocytes in the blood and in the C.S.F. On the other hand, the protein manifestations of the neurological lesion point to the fact that the brain and the spinal cord were involved. This should therefore be considered as a case of encephalomyelitis complicating an acute mononucleosis of a rather unusual type.

Had the sheep-cell agglutination test not been performed, the cause of the illness might have been missed. It is certainly worth while having a Paul-Bunnell test done in all cases showing acute neurological manifestations without apparent cause.

Sympathectomy in the Treatment of Peripheral Vascular Sclerosis

By G. DE TAKATS *et al.*

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 8th June, 1946, p. 495)

A GROUP of 25 patients suffering from vascular sclerosis of the lower extremities were treated with lumbar sympathectomy if after preliminary block of the lumbar sympathetics the temperature of the digits rose, if walking ability improved and if generalized vascular involvement was not extensive.

In one group of patients this resulted in a dramatic increase in walking ability.

In another group of patients given lumbar sympathectomy amputation was averted.

In a third group amputations could be performed at lower levels and in a fourth group intractable neuritic pain of the causalgic type was benefited.

In selected cases of peripheral arteriosclerosis lumbar sympathectomy has proved to be of great value.

A Clinical Syndrome following Exposure to Atomic Bomb Explosions

By P. D. KELLER

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 8th June, 1946, p. 504)

TWENTY-ONE patients who developed a delayed illness following their exposure to atomic bomb explosions in Japan were studied. The data on these few patients seem to indicate that the possibilities of developing this syndrome is not significantly affected by distance from the centre of the explosion as long as one is within a 2,000 meter radius. It is undoubtedly significant that only one patient is known to have been outdoors when the explosion occurred, and therefore people inside buildings were more apt to suffer from the delayed effects of atomic bombs provided they survived the initial effects. The delayed malady to some degree results from a generalized disturbance in human physiologic function, but the effects can be attributed principally to destruction or suppression of elements of the hemopoietic system (mainly granulocytes and thrombocytes) and to disturbance in liver function. The former effect produces a leukopenia (principally a granulocytopenia), thrombocytopenia, increased bleeding time and hemorrhagic tendencies with a resulting anemia, fever and weakness. The latter effect on the liver produces an albuminuria, tyrosinuria, hypoproteinemia, positive indirect van den Bergh reaction, jaundice and fever. The rapid sedimentation rate of erythrocytes gives evidence of extensive tissue destruction within the body. The similarity of this illness to that following excessive irradiation of the body with x-rays is striking.

Canities and Alopecia in Children associated with Avitaminosis

By A. P. CHAVARRIA *et al.*

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 9th November, 1946, p. 570)

IN Costa Rica infants and young children with severe avitaminosis, especially vitamin A deficiency, pellagra, riboflavin deficiency, beri-beri, nutritional edemas or mixed avitaminosis syndromes, have been observed to exhibit characteristic associated changes in the hair, loss, diffuse or in the frontal area, and changes in the hair resemble those reported previously by Trowell, Kirk, Williams, Gillman and Gillman and others in the syndrome of infantile pellagra in South Africa. These changes are easily reversible if the patient survives the severe vitamin deficiency state. Improvement may be produced by a general, adequate diet if it is utilized alone or together with poly-vitamin mixtures of the B complex.

The addition of biotin is thought, but not proved, to accelerate over other therapies the return of normal growth and pigmentation to the hair. Similar severe changes were not observed in the hair of adults with decided vitamin deficiency syndromes.

Animal Diseases and Man

(Abstracted from the *United States Naval Medical Bulletin*, Vol. 46, October 1946, p. 1599)

THE number of animal species alive on the earth has been estimated to be approximately 1,000,000.

There are about 3,500 species of mammals and 8,616 species of birds known in the world to-day. There are not more than 100 species of birds not yet discovered.

These warm-blooded animals have diseases which in some cases may be transmitted to man, and are consequently of great importance in preventive medicine. What is of almost equal importance, however, is the fact that many animals become immunized to agents not pathogenic to man in which the antibodies are curative of diseases of man.

Recently it has been demonstrated that the tubercle bacillus peculiar to voles may be used to vaccinate guinea-pigs which are then found to be protected against mammalian tuberculosis.

This of course suggests the vaccination of man with this vole-type bacillus in order to protect him against ordinary tuberculosis.

This example shows the great possibilities in disease prevention from the study of the diseases and immunization of animals from the view-point of immunity developments of value in preventing human diseases due to similar strains of causative organisms.

The Antibacterial Action of Garlic

By M. A. GOHAR *et al.*

(Abstracted from the *Journal of the Egyptian Medical Association*, Vol. 29, March and April 1946, p. 90)

THE antibacterial action of garlic is described. The active principle in it has a marked bacteriostatic action on various organisms both Gram-positive and Gram-negative, and a very feeble bactericidal one.

In high dilutions it stimulates bacterial growth and can be used as an enriching substance for the cultivation of various micro-organisms.

Its therapeutic value is doubtful.

Streptomycin in the Treatment of Influenzal Meningitis

By J. R. BIRMINGHAM *et al.*

(From the *Journal of Pediatrics*, Vol. 29, July 1946, p. 1, as abstracted in the *International Medical Digest*, Vol. 49, October 1946, p. 239)

THE report concerns eight patients ill with *Haemophilus influenzae* type B meningitis who were treated with streptomycin either from the start of therapy or following unsuccessful treatment with other therapeutic agents.

At the time the first of these patients was treated (December 1944) there was little prior experience with regard to the clinical use of streptomycin in systemic infections and none with regard to its intrathecal administration, hence the wide variation in the dosage in these patients. In all cases the streptomycin hydrochloride was injected both intramuscularly and intrathecally. The drug was dissolved in normal saline solution in concentrations of 4,000 to 5,000 units per c.c. for intrathecal use, and in concentrations varying between 10,000 and 50,000 units per c.c. for intramuscular use. The intrathecal injections were carried out twice a day, daily or on alternate days whereas intramuscular injections were given every two or three hours.

The sensitivity of the organisms was investigated in most of the cases and several spinal fluid titres were determined. For both types of determination, a crude serial dilution method was used which consisted in adding a standard inoculum of a young broth culture of *H. influenzae* to varying dilutions of either the streptomycin solution or of the spinal fluid to be tested. Control determinations were set up employing, in the earlier cases, a strain of *Eberthella typhi*, later a strain of *Staphylococcus aureus* (Smith).

Since the writers wished to obtain information with regard to the efficacy of streptomycin itself in influenzal

infections, sulfonamides and specific serum were not used simultaneously with the antibiotic. 'Either they were discontinued when streptomycin was started, or their administration was begun when streptomycin therapy was thought ineffectual, or during convalescence, when sulfadiazine was given only after the patient was apparently well of his original infection.' In one case penicillin was used concurrently with streptomycin. In two cases streptomycin was used to the exclusion of all other antibacterial therapy.

'Toxic reactions encountered include: erythema, urticaria, augmentation of meningeal signs, persistence of pleocytosis, local pain on injection, and mild shock on initial administration. None of these was serious.'

In this brief series of patients treated with streptomycin, the writers wish to point out that streptomycin is effective against *H. influenzae in vivo* as well as *in vitro*. 'In four patients the drug was extremely effective; in one it was without effect; one patient was hopelessly ill on admission; one patient showed some response despite inadequate dosage. In view of the rapid sterilization of the blood and spinal fluid in four patients without serious toxic manifestations, streptomycin appears to have a definite, but as yet undetermined, place in the treatment of influenzal meningitis.'

B.C.G. for Britain at last !

By K. NEVILLE IRVINE

(Abstracted from the *Medical Press and Circular*, Vol. 216, 27th November, 1946, p. 406)

It is now forty years since Calmette and Guérin began their search for an inoculation to protect children against tuberculosis. In 1911 they produced the B.C.G. vaccine and started to test it out on laboratory animals: in 1922 Weil Hallé began to vaccinate children in Paris: in 1934 when well over a million children in various parts of the world had been vaccinated, I first advocated its use in this country: in 1946, with the total figure of vaccinated standing at three million, we still remain one of the few countries in which the vaccine is not even obtainable.

At last, however, the tide is turning. A memorandum has been prepared by a Joint Committee of the Tuberculosis Association, the Joint Tuberculosis Council and the National Association for the Prevention of Tuberculosis advocating the introduction of B.C.G. into this country; this has been submitted to the Minister of Health and has been favourably received. We may therefore hope that the production and distribution of this vaccine will shortly be begun in this country. In view of this, I have been asked to give a brief summary of B.C.G. with detailed instruction for its practical use.

A preventive vaccine against tuberculosis has been sought ever since Koch isolated the tubercle bacillus at the end of the last century. Dead vaccines were tried at first, but these proved to be a failure. Next, live vaccines were tried, as in smallpox vaccination; experiments were made with allied forms of the tubercle bacillus, but these either proved too apathogenic to produce any immunity, as in the case of the avian tubercle bacillus, or were so pathogenic as to be dangerous, as in the case of the bovine tubercle bacillus. The only possible exception is the tubercle bacillus isolated from a vole by Wells; work on this is still in its experimental stage but the early results are encouraging.

Following these failures, in 1906 Calmette and Guérin started to attenuate a bovine tubercle bacillus by growing it on special culture media; by 1911 it had lost its virulence for all laboratory animals and succeeded in producing some immunity in them against subsequent tuberculous infection. This was then named B.C.G. (Bacille Calmette Guérin), and extensive work was done in Paris to confirm its harmlessness and effectiveness.

In 1922, Weil Hallé commenced the inoculation of children in Paris without misadventure; the popularity of the vaccine in France increased rapidly, until its

production was finally taken over by the State and it was issued free to all doctors. Simultaneously, research was springing up throughout the world from Tokyo to New York, though England still maintained a conservative attitude.

In 1927, Petroff in America alarmed the world by producing a return of virulence to the B.C.G. by laboratory methods. Following on this came the disaster of Lübeck. In the spring of 1930 a group of 249 children were given the B.C.G. vaccine at Lübeck, in Germany; by the end of the summer 73 had died from tuberculosis which was shown to have originated from the vaccine used. The use of the B.C.G. vaccine was immediately prohibited in Germany and an official inquiry was held into the disaster. Britain congratulated herself on her conservative policy and has refused to have anything to do with B.C.G. vaccination since.

Actually, it was very shortly proved that the Lübeck disaster was not due to the B.C.G. at all; an official inquiry revealed that a virulent culture of human tubercle bacilli had become mixed with the vaccine in the local laboratory, and that the original B.C.G. vaccine received from Paris was not to blame. Kirehenstein who inoculated 100 children in Riga with another portion of the same batch of vaccine had no trouble. Here it should at once be stated that the B.C.G. is by no means a 100 per cent prophylactic; at best it only raises the immunity.

Over 400 autopsies have been carefully carried out on B.C.G. children who died; in no case was there any suggestion that the B.C.G. vaccine was the cause. When one considers that at that time 1,343,000 children had been vaccinated without one sure case of death from B.C.G. infection. One feels that one would indeed be cautious if one still doubted the safety of the vaccine for the normal child. The early investigators discovered that B.C.G. vaccine could turn a tuberculin-negative child into a tuberculin positive; recently this has been used almost universally as a criterion of the effectiveness of vaccination and those children who do not become reactors are usually revaccinated. Of the various tuberculin tests the Mantoux has proved to be the most reliable, and is now generally used whenever possible.

When the vaccine was first employed it was given by mouth as being the simplest method for mass inoculation but it was soon found that only about 20 per cent of the cases became Mantoux positive. Later investigators tried giving the vaccine subcutaneously, and succeeded in raising the Mantoux positive figure to 80-90 per cent; unfortunately, this method gives a large percentage of local cold abscesses. Subcutaneous injection gave about the same number of positive reactors, but also about the same number of abscesses, and this too is now being largely abandoned. The intradermal injection of B.C.G. (with the same technique as the Mantoux) gives a slightly higher figure of reactors and a small local ulcer which may persist for 2 to 3 months; up to the last few years this has been the method of choice. Recently however Rosenthal has devised the 'multi puncture' method whereby forty needles simultaneously stab through a layer of B.C.G. into the skin; this produces a milder local reaction and up to 100 per cent of reactors. Another variation by Nègre and Bretey is to make three crosses with a vaccine stylet through drops of B.C.G., the results of this are also good.

If we assume that a positive Mantoux is essential to prove that an adequate degree of immunity has been achieved, then it is obvious that all the early oral work may be discarded as statistical evidence; only that work which has been done since the introduction of the parenteral methods need be considered. It would be thought that with all the work done there would be a considerable amount of statistical evidence to show the degree of immunity which can be produced by this vaccine. In practice, the difficulties of obtaining exact controls and of adequately following up the inoculated cases over a period of years are enormous, but the work of Heimbeck does give a typical example of the results. Heimbeck found a large proportion of

his pupil nurses became tuberculous within a short time of starting their hospital training. On testing he found that half of them had a negative Pirquet on arrival at hospital. He further found that those who showed an initial positive test had an ultimate morbidity rate from tuberculosis of 2.6 per cent, while those who were negative had a rate of 29.6 per cent. He therefore inoculated most of the negative nurses with B.C.G.; in 1927 the morbidity rate in the B.C.G. group had dropped to 2.3 per cent. It is impossible to draw clear statistical figures for the effectiveness of the B.C.G. from most of the work done, partly because of the incompleteness of the experiments and partly because of the varying conditions; in particular, the conditions under which the vaccinated and the controls live are rarely strictly comparable. One's impression was that B.C.G. at least doubled the natural immunity of the average European or American child.

As regards the B.C.G. itself, this will probably be issued in ampoules. As it is a live vaccine it must be used before it dies, or even before deterioration sets in; the exact date of the commencement of deterioration is still a debatable point, but it is safe to say that, kept in a cool place, it will maintain its full potency for ten days.

In conclusion one would say that the procedure is as simple and safe as smallpox vaccination; the degree of immunity produced is, unfortunately, not nearly so great, but it is sufficient to make one wonder why it has so long been withheld from the British child.

Permeability of the Human Placenta to Isoantibodies

By ALEXANDER S. WEINER, M.D.
and
EVE B. SONN

(Abstracted from the *Journal of Laboratory and Clinical Medicine*, Vol. 31, No. 9, September 1946, p. 1020)

Two cases of erythroblastosis due to A and B sensitization are described. Comparative titrations of the alpha and beta antibodies in the sera from both cases were carried out by the agglutination and conglutination techniques. In the titrations carried out by the agglutination technique, it was found that the ratio of the antibody titres of the maternal and infants' sera was 8 : 1 in case 1 and 64 : 1 in case 2. On the other hand, in tests carried out by the conglutination technique, the ratios of the titres approximated unity. The reason for the discrepancy is that the two tests measure two different sorts of antibodies. The former test detects bivalent antibodies (agglutinins), while the latter test also detects univalent antibodies (glutinins). These results demonstrate, therefore, that glutinins traverse the placenta far more readily than agglutinins, in accordance with the expectations under the hypothesis that the former are comprised of smaller molecules.

It may seem somewhat puzzling that in both cases the univalent beta antibodies were more readily demonstrable in the maternal serum by the conglutination method than were the univalent alpha antibodies. The following plausible explanation for this apparent paradox suggests itself. It would be expected that univalent antibodies in general would continue to pass through the placenta from mother to foetus until their concentration in the foetal circulation became equal to that in the maternal circulation, thus setting up an equilibrium. In the case of beta antibodies, such an equilibrium could be reached quickly, but in the case of the alpha antibodies, the antibodies would be neutralized or absorbed by group substances in the group A foetus' body, delaying the attainment of equilibrium and at the same time gradually depleting the mother's body of the alpha antibodies.

The fact that in both cases described in this paper first-born infants were erythroblastotic calls for some comment. In the first case, the patient stated that

two years previously she had had an ovarian tumour removed and was given several post-operative transfusions of commercial, pooled human plasma. With regard to the second case, the source of the sensitization could not be traced as definitely. However, it should be pointed out that A-like and B-like antigens are ubiquitous in nature, so that there would be many opportunities for A-B sensitization to occur in the course of a lifetime. For example, such antigens are present in horse serum and pig pepsin, so that injections of therapeutic horse serum or diphtheria toxin-antitoxin could bring about A-B sensitization. Moreover, such antigens are present in many bacteria and animal parasites, so that certain infections could cause A-B sensitization. The second patient did give a history of a severe attack of pneumonia several years before her first pregnancy, and possibly this was the source of her sensitization.

Lymphocytic Choriomeningitis

By B. R. SREENIVASAN

(Abstracted from the *British Medical Journal*, ii, 19th October, 1946, p. 573)

LYMPHOCYTIC choriomeningitis is a disease that occurs not uncommonly in Singapore, and, unless one is on the look out for it, cases might easily be missed. Headache was complained of in only 4 cases and neck rigidity in but 5 cases out of 8; only 2 had a positive Kernig's sign. One of the cases was simply a pyrexia of unknown origin, and there was no symptom or sign pointing to the central nervous system; this case would certainly have been missed if a lumbar puncture had not been done. It would therefore be advisable to bear this disease in mind when dealing with any obscure case with fever, headache, giddiness, or vomiting. There was no history of a similar illness occurring in the household or intimate contacts of these cases; none of them showed any evidence of infection of the ear, nose, or throat; and there were no sequelae.

The findings may be briefly summarized as follows:

1. Duration of illness: 2 to 21 days (average 7).
2. Race incidence: 5 Indians, 3 Chinese.
3. Age incidence: 19 to 42 years (average 27). It must be recorded here that only adults, as a rule, were admitted to these wards.
4. Number of days in hospital: 11 to 29 (average 19).
5. Fever: present in 6 cases.
6. Headache: present in 4 cases.
7. Giddiness: present in 2 cases.
8. Vomiting: present in 1 case.
9. Weakness of legs: present in 1 case.
10. Mental symptoms: present in 2 cases.
11. Hyperaesthesia: present in 1 case.
12. Neck rigidity: present in 5 cases.
13. Kernig's sign: positive in 2 cases.
14. Cerebrospinal fluid: (a) Cell count varied from 152 to 900 per c.mm. (b) Sugar varied from 10 to 84 mg. per 100 ml. 5 out of the 8 cases were between 45 and 60 mg. per 100 ml. (c) Chlorides varied from 627 to 745 mg. per 100 ml.
15. Cases not treated with sulphanilamide spent an average of 22 days in hospital, whereas those treated with it stayed there for an average of 16 days. From these figures it is impossible to draw any definite conclusion as to the therapeutic value of sulphanilamide, but the clinical impression was that cases seemed to benefit from its use.

A brief account of the literature of lymphocytic choriomeningitis is given, with reference to the clinical picture, aetiology, and pathology of the condition.

As no cases have so far been actually reported in Asiatics, 8 instances of the disease are described.

All the cases were seen at the General Hospital, Singapore. The cases conformed to the characteristics described by Gibbens (1931).

Hens' Eggs and Salmonella Infections

(Abstracted from the *British Medical Journal*, ii, p. 583)

WHILE outbreaks of food poisoning implicating hens' shell-eggs are excessively rare, J. Watt described an outbreak of twenty-eight cases of food poisoning on board a merchant vessel due to *S. montevideo* in hens' eggs eaten in a salad. The strain was isolated from several of the unused shell-eggs. M. Crowe in this country has described a small outbreak of food poisoning very probably caused by a hen's egg. The case against the duck is not only that pathogenic salmonella strains are found but that ducks are liable to infection with these strains, and the organisms are then present in the egg yolk. Certain varieties of duck seem to be especially liable to this infection. So far this chain of evidence seems to be lacking for the hen. The nearest approach to it is contained in an important paper by R. F. Gordon and A. Buxton dealing with the isolation of *S. thompson* from outbreaks of disease in chicks. This strain is a fairly frequent cause of food poisoning in man. The authors isolated it during 1943 and 1944 on forty-four occasions from thirty-one outbreaks in chicks and two in ducklings. This organism was isolated from the intestinal tract of two adult fowls but not apparently from the interior of any eggs.

Many more investigations are necessary before any final opinion can be given, but the present position seems to indicate that fowls can harbour salmonella strains which are potentially pathogenic to man. There is no evidence, however, that specific infections with these strains can infect the egg yolk, as in duck's eggs. Their presence in hen excreta explains how in dried egg mixtures it is possible to find pathogenic salmonella strains. The method of preparation of dried egg powder, if inadequately supervised, may facilitate infection. The health hazard from individual hens' eggs seems to be negligible, while that from dried egg powder is much more considerable. Investigations have shown that the drying during manufacture reduces the risk very much but does not eliminate it entirely, and there is always the possibility of infection after drying. A high standard of cleanliness and care in the factory is necessary, as are measures to exclude unsound eggs. A good deal is being done in this direction.

The Sanitary Control of Ice-cream

(From the *British Medical Journal*, ii, 19th October, 1946, p. 584)

THAT freezing kills bacteria is a fairly common misconception. Actually there is no better method of preserving their life for long periods: this is true at least of all those which enter the body by the alimentary route. Ice-cream will therefore contain in the living state the original flora of its ingredients, which may include pathogens if any cream or milk enters into its composition, and—which is more important—those introduced by insanitary methods of handling. Outbreaks of intestinal infection conveyed by ice-cream have been numerous, and regulations have been in existence for some years requiring the registration and inspection of premises used for the preparation of ice-cream. Unfortunately the resumption of its manufacture after the end of the war has been followed by an extensive outbreak of typhoid fever at Aberystwyth due to the contamination of his product by a vendor who is a urinary typhoid carrier. A similar incident has recently been followed by an equally extensive outbreak of paratyphoid B at Coatbridge in Lanarkshire. In view of these occurrences it was evident that further statutory precautions were required, and the Minister of Health has now issued a Draft Order [Draft, dated 8th October, 1946, of the Ice-cream (Heat Treatment) Regulations, 1946], the effect of which, in short, is that the mixture of which ice-cream is composed must be pasteurized before freezing. It may be heated either to 150°F. (65.5°C.) for 30 minutes or to 160°F. (71.1°C.) for 10 minutes. Further regulations

govern the subsequent cooling process and the maintenance of a sufficiently low temperature thereafter. These requirements do not apply when a 'complete cold mix powder' is used, supplied in air-tight containers and manufactured from previously heat-treated material: this may be made up with 'wholesome drinking-water', and colouring or flavouring materials, fruit, nuts, or chocolate, may be added without subsequent pasteurization. In a Circular (183/46) of the same date the Ministry of Health calls attention to these draft regulations and points out that local authorities have already considerable powers in connection with the manufacture and sale of ice-cream under the Food and Drugs Act, 1938, and refers to the possibility of defining bacteriological standards to which the product shall conform. Although it has been represented to the Ministry that laboratory tests of cleanliness are desirable the conclusion reached is that 'no test has yet been devised of the safety of ice-cream, and there is no known test which would be sufficiently reliable for use as a statutory test of its contamination with non-pathogenic organisms'. In the present state of knowledge of this subject it might well be premature to define statutory tests, but a very good idea of the hygienic quality of ice-cream can be obtained by performing a total bacterial count, a coliform count, and the identification of the coliforms as of excremental type or otherwise. The performance of some such tests on the future heat-treated product may also indicate whether the new regulations afford an adequate safeguard. The neglect of elementary precautions in handling and in ensuring the cleanliness of utensils may still presumably lead to serious contamination, if only on a reduced scale.

The 'Doctor' Sign on Cars

(From the *British Medical Journal*, ii, 19th October, 1946, Supplement, p. 101)

THE retention of the 'Doctor' sign on a good many cars has led to quite heated discussions in some quarters. The sign was introduced originally for use in extreme national emergency, but its display now would be hard to justify in many cases. It is not uncommon to find the sign on many cars parked outside a hall where the local doctors are holding a meeting and it has been seen outside social clubs where the doctor was certainly not attending in a professional capacity. No doubt some case could be made out for its retention because many journeys of the doctor's car are as urgent as those of the ambulance, which carries its own designation. At the same time the use of the sign on ordinary occasions suggests a priority which may be resented by other road users on important business and is not desired by a very large number of doctors. The Executive Committee of the Stratford Division of the B.M.A. has passed a resolution condemning the continued use of the sign and asking the Council to take some action which would discourage it.

The Life and Death of the Red Blood Corpuscle

(Abstracted from the discussion on the above subject reported in the *Proceedings of the Royal Society of Medicine*, Vol. 39, No. 11, September 1946, p. 755)

SHEILA T. CALLENDER referred to their recent work on the life of the red cell. This work was concerned with an attempt to establish a norm for the Ashby technique by the process of bleeding and immediate transfusion of healthy volunteers. The subjects were 6 male medical students and 4 women working in the department. They all belonged to group A or B and were Rh positive. Two of the men were excluded from the final results, one because he developed a small pleural effusion, presumably tuberculous, and the other because he had a transfusion reaction due to the use of a 'dangerous universal donor'. It was found

HAEMORRHOIDS

*No false
security in treatment*

No narcotic, analgesic or local anaesthetic drugs enter into the composition of Anusol Haemorrhoidal Ointment, so that it may safely be prescribed for patients of all ages without fear of rectal

absorption of any toxic substance. Anusol Ointment contains mildly astringent medicaments in an emollient base. It relieves rectal congestion, allays irritation, and soothes inflamed tissues.

Convalescence

The building up of the system after illness, especially when anaemia and emaciation are present is definitely aided by the tonic—reconstructive action of Waterbury's Compound. This preparation presents products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extract and hypophosphites in a palatable form suited to the most fastidious palate. Waterbury's Compound improves the appetite and strengthens the digestive functions.

ATERBURY'S COMPOUND

THE NEUTRALIZATION OF EXCESS ACIDITY

In conditions where eupepsia is lacking, with consequent gastric and intestinal disturbances, Cal-Bis-Ma is indicated. Cal-Bis-Ma has demonstrated its usefulness as a gastric antacid in minor gastric upsets. For the control of excessive acidity and as a protective in peptic ulcer, as well as a gastric sedative in simple nausea of pregnancy (morning sickness), Cal-Bis-Ma has achieved a reputation of its own with many physicians who have found that Cal-Bis-Ma meets the situation in a most substantial manner.

VITAPHOR

indicated in all cases of
VITAMIN DEFICIENCY

VITAPHOR—the perfect TONIC is standardised to contain the following active Vitamins in each fluid ounce :

B₁ 450 International Units
C 1300 International Units
D₂ 1650 International Units

Without these essential vitamins normal health cannot be maintained. Vitaphor also contains the Glycerophosphate of Sodium, Potassium, Strychnine and Magnesium all combined in a suitable base which gives to this Tonic a pleasant and agreeable taste. Prescribe Vitaphor in all cases of Convalescence from acute illness in cases of undevelopment, faulty Nutrition and all "run down" conditions when the body is in a low state of health.

consistently that the average life of the transfused red cells is about sixty days and that the rate of destruction is 0.83 per cent of the initial amount per day. The average life after transfusion is thus half the normal, since the transfused cells are of all ages and have already lived 60 days on the average.

Dr. J. F. Loutit discussed the survival or transfused normal red cells in recipients with hypochromic anaemia, Addisonian anaemia and acholuric jaundice, both congenital and acquired; also the survival of red cells transfused from donors with Addisonian anaemia and acholuric jaundice to normal recipients. In 1944 Brown, Hayward, Powell and Witts studied, by the Ashby technique, the survival of transfused normal red cells in 6 cases of idiopathic hypochromic anaemia. Their results showed a nearly constant rate of destruction with an average life of the transfused red cell of just over 50 days. Ashby in 1921 followed the survival of transfused group O red cells in 4 group A recipients with pernicious anaemia. In two of the cases elimination of the transfused red cells appeared to be complete by the 91st and 100th day respectively. In the other two, elimination was not quite complete at the 83rd and 100th day. Wearn, Warren and Ames repeated the experiment in 4 recipients with pernicious anaemia in 1922 and found that the transfused red cells survived for 59 to 113 days. The results of Ashby and Wearn *et al.* were obtained before the institution of liver treatment. In 1944 Brown *et al.* noted one case of true Addisonian anaemia responding to liver and showed that the survival of the transfused red cells was of the normal linear type. Dr. Loutit himself had the opportunity of transfusing with blood stored in acid citrate-glucose solution 5 cases of true Addisonian anaemia responding to liver and following the survival of the transfused red cells. These cases showed a 50 per cent survival of the transfused red cells at an average of 40.5 days. This is rather less than the corresponding figure of 60 days obtained by Mollison and Young for blood 0 to 4 days old in 15 recipients with hypochromic anaemia. Dr. Loutit's conception was that the red cells of pernicious anaemia cases are discharged from the marrow with faulty protoplasm, due to the liver principle deficiency, and being faulty are as unduly susceptible to destruction in the circulation of pernicious anaemia cases as in a normal person. The survival of red cells from 4 cases of acquired acholuric jaundice was substantially normal, 50 per cent survival being greater than 50 days in all 4 cases.

A Case of Addison's Disease Successfully Treated by a Graft

By L. R. BROSTER

and

H. GARDINER-HILL

(Abstracted from the *British Medical Journal*, ii, 19th October, 1946, p. 570)

AN account of a girl with Addison's disease is given. The grafting into this patient of a hypertrophied adrenal gland derived from a woman suffering from the adreno-genital syndrome (hyperplasia) is described.

The diagnosis of Addison's disease in this girl was based on the classic clinical-picture-typical asthenia, pigmentation, gastro-intestinal symptoms, and low blood pressure. When she originally came under Dr. Wetherell's observation for this condition her blood sodium was 310 mg. per 100 ml.; six months later it had fallen to 284 mg. per 100 ml. When she came under our observation three months later she was taking extra salt and was on substitution therapy; an initial sodium withdrawal test for a week resulted in her blood sodium falling to 295 mg. per 100 ml., and her blood pressure to 95 systolic. We considered that the diagnosis of Addison's disease was established.

The patient's condition changed satisfactorily after operation, and in our opinion, as a result of it. Sodium

withdrawal tests carried out for a week at a time at intervals as above stated showed that she no longer reacted to withdrawal of extra salt by a fall in blood sodium or a fall in blood pressure. In fact, in the first two sodium withdrawal tests in May and October, four and nine months after the operation, the blood sodium rose rather than fell at the end of the week's extra salt withdrawn, while the blood pressure remained at about the same level. In the final test, just over a year after operation, the blood sodium remained at a steady level after extra salt withdrawal, and the blood pressure was slightly higher at the end of this week's test. The results of these tests were obviously entirely different from the results of the tests before operation, and we felt it reasonable to assume that the cortical deficiency had been corrected. This was confirmed by the fact that following the final test the patient was able to leave off extra salt and carry on without any treatment at all. The last blood sodium reading, after three weeks of all treatment, was well within the normal limits, while her blood pressure at this time was actually showing readings that had never been recorded before. As a result of what we considered to be emotional reaction when her blood pressure was taken, readings as high as 180 systolic were found.

The results, therefore, of the grafting operation appear to have been extremely satisfactory, and if one can accept the blood sodium levels in similar salt withdrawal tests before and after operation as an indirect indication of the state of the cortical-deficiency sodium leak, it would appear that the latter has been compensated by the adrenal graft. It was unfortunately impossible to get the measure of the leak by urinary sodium and chloride excretion estimations, but it would certainly have been interesting to have noted whether there was any raising of the renal threshold during the tests as an explanation of the high sodium figures noted after the second and third tests.

Further follow-up data will be published in due course, but as it is now over a year from the time of the operation, we are hoping that the improvement will be maintained.

It is to be noted that in spite of the fact that this patient was grafted with an adrenal from a patient with the Addison's disease, there is no evidence of that in her case, and her menstrual cycle remained regular throughout the period of observation following operation. Her 17-ketosteroids were estimated about two months after the operation and found to be within the normal range of 10.3 mg. a day.

Reviews

ORAL MEDICINE—DIAGNOSIS AND TREATMENT.

—By L. W. Burket, D.D.S., M.D. 1946. J. B. Lippincott Company, Philadelphia and London. Pp. xxvii plus 674, with 350 illustrations, 60 in colour on 10 plates. Price, 72s.

THERE is some truth in the author's statement that the importance of the oral cavity as an indicator of the general health of an individual has not been sufficiently appreciated. Too often the physician's examination consists in a cursory glance at the tongue or the tonsils and the dentist's activities are confined to mechanical operations only, yet a careful examination can throw much light on the patient's general condition. In this respect the dentist has a unique opportunity to recognize the earliest signs of many diseases and can co-operate with the physician to the great benefit of the patients, though he need not concern about treatment except in so far as it depends on dental care. This book which is primarily meant for dentists is designed to encourage this sort of co-operation. It discusses the oral aspects of various systemic diseases

and also the remote effects due to infection or other conditions in the mouth. The ætiology, diagnosis and treatment are described in various sections of the book, but we cannot understand why typhus fever, botulism and tetanus have been included under gastro-intestinal diseases. Though practical, the book is a little too comprehensive and in our view those diseases which have doubtful dental implications might have been excluded. There is a chapter on focal infection and many will agree with the author's conclusions. Other chapters deal with laboratory procedures, hazards of dental practice and oral aspects of aviation medicine. The book is profusely illustrated, and there is a coloured atlas of lesions commonly encountered in daily practice, followed by a diagnostic index. Dentists will find it interesting and instructive.

R. N. C.

EDINBURGH POST-GRADUATE LECTURES IN MEDICINE. Volume Three. (1942-43.) Published for the Honyman Gillespie Trust by Oliver and Boyd, Edinburgh. Pp. xi plus 387. Illustrated. Price, 15s.

This volume contains thirty-two lectures delivered in 1942-43 by a team of specialists under a grant from the Trustees of the late Mrs. Honyman Gillespie, the delay in publishing being due to paper shortage. The subjects are varied and cover a wide field, being such as sciatica, cerebro-spinal fever, chemotherapy, cancer, control of sepsis, intestinal obstruction, air-borne infection, diet, delinquency, deafness, etc. The lectures provide a reliable survey of the advances and attainments in the chosen subjects. The price is moderate.

R. N. C.

TUBERCULOSIS AND CHEST DISEASE FOR NURSES.—By G. S. Erwin, M.D. 1946. J. and A. Churchill Limited, London. Pp. vii plus 236. Illustrated. Price, 10s. 6d.

This book on Tuberculosis and Chest diseases is very well written, the different stages being clearly set out and easy for the probationer nurse to follow. Though at the moment there is still no special part in Nursing Council Registers in this country for the tuberculosis trained nurse, the day is fast approaching when there will be, and even now there is, from the study of such a book as this the probationer who is doing General Training can benefit very greatly.

P. B.

ILLUSTRATIONS OF ANATOMY FOR NURSES.—By E. B. Jamieson, M.D. Second Edition. 1946. E. and S. Livingstone, Limited, Edinburgh. Pp. 64 plus 8 Index pages. Price, 8s. 6d.; postage, 6d. (home)

This collection of anatomical illustrations is really wonderful; any nurse lucky enough to possess it will find it invaluable in learning her lectures. It is beautifully produced and very handy. It should be strongly recommended to nurses in all training schools.

P. B.

BACTERIA IN RELATION TO NURSING.—By C. E. Duke, M.D., M.Sc., D.P.H. 1946. H. K. Lewis and Company, Limited, London. Pp. viii plus 186 with 20 illustrations including 12 in colour. Price, 12s. 6d.

An excellent manual of instruction for the nurse who intends to devote her energy towards teaching and useful to the Sister Tutor who has to explain the science of Bacteriology to student nurses. A book to be recommended for the library of all Sister Tutors.

P. B.

AIDS TO TRAY AND TROLLEY SETTING.—By M. Houghton, S.R.N., S.C.M., D.N. (Lond.). Third Edition. 1946. Baillière, Tindall and Cox, London. Pp. xiii plus 210. Illustrated. Price, 5s.

A VERY useful pocket book for any nurse or general probationer. The description of the various Tray and

Trolley sets is clear and concise, and a nurse ordered to prepare for any of the treatments so described can with the help of this useful manual do so quickly and accurately. The glossary of instruments is particularly useful to the young student nurse. I would recommend this book to all nurses.

P. B.

PATIENTS AND APPENDICITIS.—By Sir Crisp English, K.C.M.G., F.R.C.S. 1946. J. and A. Churchill Limited, London. Pp. vii plus 155, with 4 figures on 2 plates. Price, 10s. 6d.

This compact little book, written essentially to give the general practitioner the outlook of the surgeon on appendicitis, certainly achieves its objective.

Within the compass of twelve very readable chapters a complete survey of the subject is made and a surprising amount of detail included.

Beginning with a delightful essay on patients, which no doctor or surgeon in active practice can afford to miss, the standard thus set is steadily maintained. The size of the book calls for dogmatism found in places but without detracting from the usefulness of the whole.

The plea for wider education of the general public in matters of the Acute Abdomen is urgent and one that should receive the attention of all Public Health Departments.

There are references to caecostomy for distension and drainage for fourth and fifth day appendicitis cases which are dangerous in the reviewer's opinion, especially since their exact indications are nowhere mentioned. The use of a Miller-Abbott Tube and penicillin, sulphate treatment receives no mention.

Although the importance of charting the pulse and temperature is mentioned, that of a fluid intake-output chart is neglected.

The opinion that operation is the best hope for the general peritonitis patient will not be welcomed by all surgeons and with good reason. The choice is not one of operation or no operation, but is rather a problem of planning proper, vigorous, non-operative, treatment and of knowing when an operation is required if at all, taking the evolution of the case with consideration.

The remarks on Anæsthesia in Children are of great importance. The terror a child suffers from having anæsthesia induced whilst fully conscious is horrible, as anyone who as a child has undergone such a crude assault knows. Yet daily the atrocity is committed without a thought.

Advice on the management of the appendix mass should be accepted with much reservation in the tropics or any country where amœbiasis and tuberculosis are common.

It is a pity more attention has not been given to the bibliography. Many of the references are incomplete, and no particular method of quoting has been adhered to.

The book undoubtedly represents a summary of Sir Crisp English's personal practice in appendicitis, and, although each surgeon will develop his own practice as he becomes experienced, the book is full of wisdom derived from a long experience as a surgeon and is worthy of the attention of all general practitioners and young surgeons.

A. T. A.

RARE DISEASES AND SOME DEBATABLE SUBJECTS.—By F. Parkes Weber, M.D., F.R.C.P. 1946. Staples Press Limited, John Bale Medical Publications Ltd., Cavendish Place, London, W.1. Pp. 174

This book is meant for the mature medical man of the leisured class. He will, with its aid, revise retrospectively, the diagnosis of some of his cases.

Many rare syndromes and conditions including Ehlers-Danlos syndrome (over-elasticity of skin + over-extensibility of joints + skin-friability), Sjogren's syndrome (dryness of eyes, nose, throat and larynx),

Maccucci's syndrome (dyschondroplasia + vascular hamartomata) and Luteum Bacher's syndrome (congenital mitral stenosis + defect in inter-auricular septum; appearance suggestive of infantilism, progress good), for instance, are described.

Additional information is supplied on several well-known items such as flushing, blushing, and metabolic and endocrinal disorders.

Freud's influence (he explored dark caves and vaults of the subconscious mind, giant-wise and because of the darkness 'saw' what was not really there), euthanasia (actual pains of disease and dying have been over-estimated, and euthanasia if made legal would seldom be earnestly demanded), queer currency and latest epigrams are not omitted.

The general get-up could be better and it is hoped would be better in the next edition (slightly shorter line, wider margin and better binding).

S. D. S. G.

MEDICAL EMERGENCIES.—By Charles Newman, M.D. (Cantab.), F.R.C.P. (Lond.). Third Edition. 1946. J. and A. Churchill Limited, 104, Gloucester Place, Portman Square, London. Pp. 117

This is the third edition of a useful little book. Brief but pertinent information is given on all points connected with emergencies, with a view to enabling a general practitioner to make up his mind quickly in the face of danger.

The items discussed include poisons, newer drugs, venesection, blood transfusion, administration of opium in abdominal pain and even tracheotomy.

A medical man in general practice cannot fail to find the book useful. Blood transfusion, perhaps, he had better leave to others.

S. D. S. G.

BOOKS RECEIVED

Abstracts from Reports

ADMINISTRATION REPORT OF THE K. E. M. HOSPITAL AND G. S. M. COLLEGE FOR THE YEAR, 1945-46

Hospital.—The average daily in-patients exceeded the accommodation (510 beds), and sometimes the number was well over six hundred. The out-patients also increased both in total and average attendance. The expenditure has been steadily increasing during the last three years, especially on account of in-patients, each of whom costing Rs. 4-13-0 a day during the year under review. This does not include the cost of expensive drugs, injections, blood transfusions, etc., which were met out of the Poor Box Charity Fund amounting to Rs. 38,648. Among the pleasing features of the institution are the Nurses' Welfare Fund and the Co-operative Credit Society of the labour staff.

College.—Eighty-six fresh admissions were made, their average age being 19. It is interesting to note the occupation of their parents or guardians: 26 were dependent on 'service', 16 on business, 12 on medical profession, 4 on legal profession, 6 on pension, 3 on landed property and 19 on miscellaneous occupation. The total undergraduates were 519 including 123 female

students. According to a scheme inaugurated by the Bombay University, they were medically examined and placed in the following classes—577 in A, 42 in B and 11 in C. In the final M.B., B.S. examination the percentage of success was a little over 33. Special post-graduate classes were held, and the number of post-graduates including research students were 69. The college has been recognized for the D.L.O. and D.V.D. diplomas of the University. The report gives a list of various investigations that are going in the hospital and the college and also a list of articles published by the staff in the medical press.

R. N. C.

ANNUAL REPORT OF THE DIRECTOR OF THE PASTEUR INSTITUTE OF SOUTHERN INDIA, COONOR, TOGETHER WITH THE THIRTY-NINTH ANNUAL REPORT OF THE CENTRAL COMMITTEE OF THE PASTEUR INSTITUTE ASSOCIATION FOR THE YEAR, 1945-46

ROUTINE WORK

Antirabic Treatment

(i) Antirabic Treatment for Human Patients

DURING the year under review 18,964 courses of antirabic vaccine were issued under the revised system of treatment. Details of the revised system of treatment are given below:—

	Adult dosage	Child dosage	Number of days
Class I	2 c.c.	2 c.c.	7
Class II	5 c.c.	5 c.c.	14
Class III	10 c.c.	5 c.c.	14

Four hundred and eighty-three patients received a complete course of antirabic treatment at the Institute (469 Asiatics and 14 Europeans). Incomplete courses of treatment were also given to 82 patients.

Two deaths were recorded among the 550 patients who received complete or incomplete courses of treatment giving a mortality rate of 0.36 per cent. The deaths occurred among Asiatic patients.

At subsidiary centres 13,873 received a complete course of treatment and 3,474 were incompletely treated.

Twenty-one deaths were recorded among these 17,347 patients giving a mortality rate of 0.12 per cent.

No case of post-treatment paralysis ('paralytic accident') was reported during the year.

(ii) Antirabic Treatment for Animals

Antirabic treatment was also made available for the prophylactic treatment of animals. During the year 159,040 c.c. of 5 per cent carbolized sheep-brain vaccine were issued for the treatment of animals, and issued chiefly to veterinary officers of the Madras Presidency and the neighbouring Indian States. The number of animals treated during the year was 1,433, of which 965 were dogs.

General Laboratory Work

Routine laboratory examinations were carried out on a large scale for the benefit of hospitals, dispensaries and practitioners. The total number of examinations carried out during the year was 4,427. Most of this was done free of charge.

The Institute also continued to receive and report upon brains from suspectedly rabid animals. During 1945, 404 such specimens were received.

Blood Bank

The Blood Bank work at the Institute was continued. During the year 15,830 c.c. of plasma were prepared. Since the inception of the Blood Bank in 1942 a total

of 77,320 c.c. of plasma have been prepared and issued to various civil, military and mission hospitals.

relationship between the body weight and hæmoglobin is shown below :—

Weight in lb.	71-80	81-90	91-100	101-110	111-120	121-130	131 and over
Mean hæmoglobin in gm. per cent.	10.49	11.71	11.29	12.61	13.29	13.41	14.93

RESEARCH WORK Pasteur Institute

(i) Rabies

(a) *Studies on the cultivation of the ætiological agent of rabies in vitro and its nature.*

Rabies.—Rabies virus can be cultivated *in vitro* in a cell-free medium containing 1.5 per cent steamed sheep-brain extract, 2 per cent sheep serum, 2.5 per cent glycerine and 0.15 per cent peptone. This shows that it is not a virus in the accepted sense of the term.

(b) *Studies on antirabic immunization with culture vaccine.*

A method is described for the preparation of a culture vaccine for immunization against rabies.

(ii) Action of Heparin on Snake Venom

Heparin and snake venom.—In view of the antagonism of action of heparin and Russell's viper (daboia) venom on coagulation of blood *in vitro*, studies were undertaken to determine whether heparin would be of any therapeutic value in cases of bite by Russell's viper. *In vivo* experiments, in which heparin was given to rabbits intravenously, before venom was injected i/v or i/m, confirmed that (1) the action of heparin was as effective *in vivo* as *in vitro*, 10 mg. of venom representing over 60 lethal doses having failed to cause death in a rabbit given 5 mg. of heparin i/v, (2) heparin could be given i/v to rabbits without any untoward effect in doses up to 20 mg. per kilo, and (3) animals given lethal doses of venom i/m and subsequently treated by heparin could be saved. These findings seem to justify the therapeutic trial of heparin in cases of bite by Russell's viper, though the optimum dosage and methods of administration in human cases have to be worked out.

The action of heparin on other snake venoms, particularly of the Viperidæ family, was studied. It was found that the venoms of some vipers as *B. arietans*, *B. alternatus* and *Causus rhombecatus* are anticoagulant in their action on blood. Heparin has no action on these venoms *in vitro* or *in vivo*. The venom of *Echis carinatus* was found to be a powerful coagulant. Heparin prevented this action of *Echis* venom to some extent, both *in vivo* and *in vitro*; but it had to be used in very large quantities, approximately 75 times the weight of *Echis* venom used, unlike its action on daboia venom, which heparin could effectively neutralize, weight for weight. It could save animals only up to 20 M. L. D. of *Echis* venom injected; beyond this limit heparin was ineffective.

The venom of the Australian tiger snake (*Notechis scutatus*), though a powerful blood coagulant, was found to contain other factors, e.g. neurotoxic and cytolytic fractions. While heparin could prevent the coagulant action of this venom, it had no effect on the neurotoxic principle and hence could not save animals against more than one or two lethal doses of this venom.

Further studies revealed that heparin has no action on cobra venom and diphtheria and tetanus toxins.

(iii) Studies on Blood

Hæmatological data.—In the course of an investigation on the immunological changes produced in patients as a result of antirabic treatment, it was decided to utilize the specimens of blood collected for a hæmatological survey in addition.

Analysis of the data with a view to correlation of the hæmoglobin levels with any other factor revealed a

Further studies on (a) hæmatological standards in South India and (b) coagulation of blood are in progress.

NUTRITION RESEARCH LABORATORIES

(Indian Research Fund Association)

The analysis of foodstuffs.—The thiamin and nicotinic acid content of different samples of yeast, yeast extracts, wheat, rice, vitamin tablets and ampoules and Prosopis has been determined.

The report on soya bean has been completed and sent to the office of the I.R.F.A. for publication.

The fractionation of the nitrogen and phosphorus complex of the coconut kernel has been completed. The carbohydrate complex of the kernel is being studied.

Experiments are in progress on the loss in vitamin A content of ghee when stored under different conditions. Various animal experiments are being carried out.

Clinical and field investigations.—The work on infantile beri-beri in Cocanada has proceeded and a report on this enquiry is under preparation. While the curative effect of pure vitamin B₁ on infants suffering from beri-beri has been abundantly confirmed, a preventive experiment in which vitamin B₁ tablets supplying one milligram of vitamin B₁ were given daily to expectant and nursing mothers was not wholly successful.

An investigation on lathyrism in Bhopal State was carried out in February 1945. A paper has been prepared on this subject for submission to *I.J.M.R.*, and the attention of the Food Department has been drawn to certain aspects of the outbreak in question, and in particular to the fact that wheat procurement operations played a part in the genesis of the epidemic. The outbreak was due to the consumption of lathyrus as a staple food for six months or more, and no confirmation was obtained of the theory that a poison in the pulse *Vicia sativa* may be concerned in the causation of lathyrism.

Work on the relation between dental caries, fluorosis and nutrition was continued.

Nutrition class.—A course of lectures on nutrition was delivered to 26 officers selected by the Department of Food, Government of India.

SOUTHERN INDIA BRANCH OF THE MALARIA INSTITUTE OF INDIA (1944)

Research activities were mainly concerned with the bionomics of *A. fluviatilis*.

R. N. C.

The Indian Medical Gazette Fifty Years Ago

LONDON LETTER

(Reproduced from the *Indian Medical Gazette*, 1897, Vol. XXXII, p. 107)

THE excessive and increasing prevalence of venereal diseases in the European army located in India is

exciting much attention at the present time. It is recognized that not only are these diseases a serious cause of disablement and inefficiency in the army, but that they are also a veritable and grave cause of degradation of the constitution and health of a substantial and growing proportion of the civil population of Great Britain. The policy of ignoring prostitution and its effects and taking no thought or action to prevent this class of preventable maladies is becoming discredited, and the Press, medical and lay, is beginning to clamour for prompt and effective repressive measures. A very strong and cogent article has been extensively and approvingly quoted from the *Allahabad Pioneer* in which the necessity of interference is clearly proved. It is whispered that this view has been pressed on the government from exalted quarters, and a strong committee, under Lord Onslow, is at present engaged in taking evidence on the subject and paving the way, it is noted, for resolute action. Suppressing prostitution by ignoring it is a vain and foolish expectation, contradicted by all history and now signally disproved by this large and disastrous experiment by which so many lives have been blighted, and the constitutions of so many innocent persons ruined. These maladies no doubt arise from abuse of a natural function, but this fact does not act as a deterrent against vice nor as a means of controlling those instincts and impulses which next to the love of life are undoubtedly the strongest animal motives. If what may be conceded to be the natural punishment of abuse and vice fails to deter, the main, if not the sole, argument in support of the *laissez faire* policy falls to the ground. On the contrary, even from the purely moral point of view, the opposite policy of recognizing and regulating has been proved by experience to have a more deterrent, suppressing and rescuing influence than the others. That most dangerous species of prostitution, the clandestine, is minimized, and many women thus prevented from entering on a career of open dissipation and debauchery, and means are placed at the disposal of the benevolent of bringing salutary influences to bear on those who have entered on a life of vice and of persuading and assisting them to abandon a loathsome and irksome servitude to passion and turn to quiet and useful modes of earning a livelihood. The moral argument when extended is entirely in favour of preventive and repressive measures. Venereal disease is not the only physical consequence of moral ill-doing. Physical evil is largely, if not mainly, the outcome of sin of some sort, yet it has not, on that account, been considered sinful to take thought and effort to prevent and control. No doubt the real remedy consists in going to the fountain head and cleansing the spring; but this cannot be accomplished by folding the hands, standing aloof, and simply watching the operation of cause and effect. Efforts to avert physical evil necessarily imply restriction as regards the causes, and in this particular case, the deprivation of liberty to infect and the restoration to health both include actual suspension, if not abolition, of vice in its most reckless and abominable forms. The principle of prevention is the same as in the case of any other disorder communicable from one human being to another, namely, segregation, as long as infectiveness continues. For the purpose of segregation, notification or detection is necessary. These principles should theoretically apply equally to men and women who become contaminated and dangerous. They are more easily applied to women who make prostitution a profession; but there ought to be no difficulty in the army in dealing with diseased men for the purpose of rendering the spread of disease less easy than it is. That something must be done to prevent the British army from continuing to be a forcing bed of nasty complaints seems quite certain, and the sooner the better.

The examinations for the Army Medical Staff and Indian Medical Service are in progress. Forty-one candidates have come forward to compete for thirty-five vacancies in the former, and twenty-four for seven vacancies in the latter. It is satisfactory to find that the boycotting of the Army Medical Department seems

to be at an end. Some concessions as regards leave and pay have been made, and others will probably follow in time. Surgeon-Major-General Jamieson in his address at Netley at the close of the last session made some very sensible remarks on agitation for the redress of service grievances. He especially condemned anonymous attacks on the authorities in medical and service journals by medical officers on the active and retired list. Grievances exist in every service, civil and military, and open and constitutional methods exist of representing them. The worst method of attempting to procure relief is setting the backs of the authorities up by intemperate and violent anonymous writings. Concessions forced by such means, if indeed they ever are so obtained, are apt to be meagre, grudgingly given, and easily revoked, while a sore, unpleasant and hostile feeling towards those who descent to the use of masked attack remains. It seems better to give the government credit for a desire to exercise justice and generosity than the reverse. So far as I can learn, the present Secretary of State for War is fully impressed with the value and importance of the medical services of the army, both in peace and war, and most anxious to do all in his power to promote contentment and efficiency—conditions which are very intimately related.

The Bombay plague is being keenly watched in Europe, and a sort of panic has arisen among the nations for fear of an extension westward. An important conference is to assemble at Venice on the 16th of this month for the purpose of discussing defensive measures. Meantime resort is being made at many ports to quarantine and prevention of unloading Indian goods. I see that an authoritative declaration has been made in India that plague is not contagious. No doubt this is quite true in the restricted meaning of the word; but that the disease is communicable from man to man and community to community and portable by human agency cannot be denied; no good can come of absolute denial such as I have referred to, nor can resort to precautionary methods of averting the spread of plague be condemned. The only question really is, what methods are best. The choice lies between the discredited and antiquated system of quarantine which is favoured by European powers, and the English system of early and exact information, thorough inspection, isolation of the infected and subsequent watching of the rest—as was recently so successfully put in practice in the case of the *Nubia*.

12th February, 1897.

PRECAUTIONS AGAINST PLAGUE

(Reproduced from the *Indian Medical Gazette*, 1897, Vol. XXXII, p. 101)

NOTWITHSTANDING the efforts that have been made by the authorities on the western side of India, the epidemic of plague has continued to spread in different directions, and wherever the disease has taken root, it shows no signs of abatement in virulence. There can be no doubt that Bombay was taken by surprise, and, when it was realized that plague had invaded the city, the desire not to damage the many interests involved, and the mistaken notion that it was a disease of locality and unlikely to spread prevented the authorities, local and imperial, from taking those radical measures which alone could be relied upon to stamp out and check the commencing epidemic. It is gratifying to record that there was one exception amongst those in authority who took a broad and statesmanlike view of the situation and at once advocated measures which, had they been agreed to and carried out, would in all probability have limited the extent of the epidemic. We refer to Sir Alexander Mackenzie, the Lieutenant-Governor of Bengal. His recommendations were made early in October last and recently repeated in his very able speech in Council. And it must be a source of satisfaction to him to

find that his recommendations, though tardily accepted, are gradually being introduced.

The gravity of the situation is now beginning to be understood even by the most sceptical; and public alarm has emphasized the necessity for action, and not a moment too soon. The danger is not a local one, and the first consideration of government should be to protect the unaffected parts of India; for, should the disease succeed in becoming generalized throughout India, it will not only ruin this country but give such an impetus to the epidemic as to render it a danger to every country in communication with the East. The measures recently taken, though excellent in themselves are hardly, we think, commensurate with the present needs of the situation. The medical inspection of railways, the prohibition of pilgrims from infected areas, quarantine of ships from infected ports, the prevention of the importation by sea of rags, used gunny bags, etc., and the adoption of the policy of segregation camps, are all measures in the right direction, the most important of which we have insisted upon since the disease appeared in Bombay. The passing of the Epidemic Diseases Act gives full power for the carrying out of any measure which may be considered necessary. The time has more than arrived for further stringent precautions, and the government and local authorities ought to be in advance of public opinion in these matters. No necessity should arise for an agitation such as occurred in Madras and Calcutta on the pilgrim question. It is a dangerous policy from every point of view to delay effective action until it is actually forced upon the authorities by outside opinion.

Apart from the dangers to which a district or town within a few days' journey from an infected area is subject from omission of the most stringent measures possible to prevent the introduction of the disease, there is the danger of loss of trade by the action of Foreign Governments who are likely to treat India as one infected centre. Unless, then, the infected areas in India are thoroughly isolated and rigorous measures are taken by the authorities to prevent the extension of the disease into those parts of the country which are marked out as uninfected, it is to be feared that a heavy blow will be dealt to the country at large, and Indian ports quite free of infection will be quarantined. This action on the part of Foreign Governments is no doubt unwarrantable, but it is one which must be considered and dealt with. This is no mere supposition. Dr. Brouardel, the sanitary adviser to the French Government, who has much influence in International Councils, has expressed his views very strongly on the subject. It is for the Indian authorities to disarm criticism by showing that the infected area, which is still extremely small, is cut off by a rigid system of land quarantine including the disinfection and prohibition of certain goods suspected of carrying infection from infected areas. With this done there can be no reason for placing under quarantine any Indian port, except Bombay and Karachi. No doubt, the carrying out of these measures will cost money and give trouble; but whatever it may cost, and whatever trouble it may give, they are insignificant when compared with the loss which would be incurred if Indian ports were placed under stringent quarantine rules by Europe.

Correspondence

HELMINTHAGOGUES

Sir,—Ref. Dr. Rai's article in your *I.M.G.* of October 1946, p. 447, about sulphapyridine and sulphathiazole as helminthagogues, I think that some other drugs also have a similar action.

When treating an enteric case with mist chlorine some years ago, the patient, a boy of 12 years, passed

a number of roundworms on the 2nd or 3rd day of the chlorine treatment. I then started prescribing this mixture as a routine in hospitals and dispensaries for worm cases, as santonin was so scarce and costly.

I had occasion to mention this to other doctors and they also resorted to this line of treatment in their dispensaries. I was surprised to hear from one of them that in a case of tapeworm it also expelled the entire worm. I did not know it could do this, though thread worms used to be expelled.

In case of malaria and *ascaris lumbricoides* in children, the chlorine mixture with the addition of quinine served a dual purpose.

Yours, etc.,

J. F. HENRIQUES, L.M. & S., F.C.P.S.,
B.M.S. (Retd.),
C.M.O., Rajpipla State.

IS SECOND ATTACK OF DIPHTHERIA POSSIBLE?

Sir,—Regarding above will you please permit me to refer to the following lines from Kolmer?

'One attack of diphtheria does not always confer a lasting immunity, second and even third attacks are not uncommon. This is probably because our body cells respond slowly to stimulation by diphtheria toxin with the production of antitoxin and the ordinary attack of diphtheria is too brief in duration for adequate stimulation of antitoxin production. This is indicated by the fact that several months are required for the production of sufficient amount of antitoxin after the injection of toxin-antitoxin mixture (*Infection Immunity and Biologic Therapy*—3rd Edition, pp. 860).

The incidence of diphtheria is most common in children between the ages 8 months and 8 years. This is because by 8th month the congenital antitoxic immunity conferred by the mother to the child passes off. And between the ages 8 months and 8 years the body cells being too immature. Immunity response in case of an infection cannot possibly ward off the probability of another infection during the period.

Reference is also made in Price, 'The immunity afforded by diphtheria is short-lived, relapses are not uncommon and second attacks also occur' (*A Textbook of Practice of Medicine*, 1933, pp. 104).

Yours, etc.,

H. GHOSH, M.B., D.T.M.

CALCUTTA,

17th February, 1947.

BLOOD DONATION

Sir,—I have read with interest the article on the 'Effect of Blood Donation on Haemopoietic System' by Drs. C. R. Das Gupta and J. B. Chatterjea in the August issue of the *Gazette*. As one who has come across some instances of very frequent blood donations, I welcome the article as a timely warning against such a practice. The suggestion that the interval between any two blood donations should be at least 3 months is perfectly sound and it gives even donors with a tardy haemopoietic regeneration ample time to reach their pre-donation level. This was the rule followed by the London Blood Transfusion Service before the war.

There is now no longer any doubt about the relation of food with blood regeneration. Whipple has produced experimental evidence which shows that proteins are essential for regeneration of haemoglobin and that haemoglobin production in the body can be limited not only by iron restriction but also by restriction of protein intake.

The authors' suggestion that 'the donor should be advised to take adequate animal protein for two to three weeks after each donation of blood' may not be practicable in all donors. Perhaps a more practicable procedure would be to give them a week's course of tablets of ferrous iron as is done in England but caution is necessary to avoid the suggestion to the donors (who are already somewhat reluctant) that blood donation is dangerous in that it requires medicine afterwards.

The suggestion that the donor should always be examined not only clinically but also haematologically before each donation of blood is a counsel of perfection not always capable of being followed by the blood banks. A haemoglobin estimation by a reliable technique can, however, be suggested with greater chance of being followed.

Yours, etc.,

K. S. RANGANATHAN,

Officer on Special Duty (Blood Transfusion),
Office of the Director-General,
Indian Medical Service.

REUNION DINNER

SIR,—Last year a dinner was held in London for psychiatrists who had served in India Command and A.L.F.S.E.A. There were forty present and some were accompanied by their wives. The affair was regarded as a success and it has been decided to repeat it this year.

The dinner will be in the Criterion Restaurant, Piccadilly Circus, London, W.1., on Saturday, 21st June, 1947, at 7-30 or 8 o'clock. Several Indian psychiatrists, members of the I.A.M.C., are temporarily in London; and this letter may catch the eye of others who propose to be in the U.K. during the summer on holiday or for post-graduate work.

I shall send further details to any who ask me. The cost of the meal will be about Rs. 10. It is of course necessary to know numbers ahead of the date.

At the last dinner there were numerous enquiries about our Indian colleagues, but unhappily our information was sparse. I shall be delighted to hear from any of them who cannot be at the dinner and to pass on their news to their friends here.

I am, Yours, etc.,

E. A. BENNET

(previously Consultant in Psychiatry,
India Command).

Any Questions

USE OF D.D.T.

SIR,—Could you kindly let me know through the I.M.G. the reply to the following questions:—

(1) The strength in which the commercial D.D.T. solution may be sprayed as an effective domestic insecticide.

(2) The diluent recommended for the purpose so as not to spoil clothes, books and other household articles.

(3) Quantity of diluted D.D.T. to be used in a spray and its frequency so as to eliminate insects effectively.

(4) Ways and means to get rid of the poisonous effects of D.D.T. when utensils and human body have contacted it.

Yours faithfully,

P. K. GHOSH, M.B. (Cal.).

BABHIVAN,

Dist. GONDA, U. P.,
16th February, 1947.

(1) and (2) 5 per cent solution prepared in crude kerosene oil.

(3) The quantity required will depend on the area to be sprayed. The walls and ceiling should be thoroughly treated with the kerosene mixture but not bedding, clothing or garments.

Frequency: There are no fixed rules as to how frequently the spray should be used. It will depend on its action on the local insects.

(4) D.D.T. in the strength used as a liquid insecticide is non-toxic to animals. Some people show a high degree of sensitiveness of the skin; this, however, is not commonly seen.

Washing with soap and water will remove all traces of the insecticide.

D. R.

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL B. K. SHEOREY, Additional Assistant Director-General, Indian Medical Service (Resettlement), is appointed officiating Additional Deputy Director-General, Indian Medical Service (Resettlement), with effect from the 23rd January, 1947, vice Lieutenant-Colonel K. S. Fitch, O.B.E., granted leave.

The Secretary of State for India has sanctioned the reversion to military employment of Major F. C. Leach, of the Central Provinces and Berar, Indian Medical Service Cadre, with effect from the 15th November, 1946.

Major J. H. Gorman is appointed Port Health Officer, Bombay, with effect from the 29th December, 1946.

Major Aminul Haq is appointed as Deputy Assistant Director-General, Indian Medical Service (Records), with effect from the 16th January, 1947.

Captain P. W. Weston has been appointed as Medical Adviser (Pensions), with the status of D. A. D. M. S., Defence Department (Pension Branch). Dated 13th January, 1947.

The services of Captain (Miss) A. F. Hankins, Lady Medical Officer, Port Blair, were replaced at the disposal of the Defence Department, with effect from the 22nd August, 1946.

The services of Captain (Miss) L. J. N. Koehhar were replaced at the disposal of the Defence Department, with effect from the afternoon of the 13th November, 1946.

LEAVE

Lieutenant-Colonel K. S. Fitch, O.B.E., Additional Deputy Director-General, Indian Medical Service (Resettlement), is granted leave on average pay *ex-India* for 6 months under the Key leave scheme, with effect from the 16th January, 1947.

Lieutenant-Colonel M. A. Rahman, I.M.S. (Retd.), Member, Federal Public Service Commission, is granted, preparatory to retirement, leave on leave salary equivalent to full pay for 4 months, with effect from the 1st March, 1947.

Lieutenant-Colonel W. H. Crichton, Director of Public Health, C. P. and Berar, granted war concession leave on average pay from 1st November, 1946, to 16th November, 1946, leave on average pay from 17th November, 1946, to 6th January, 1947, and leave on half-average pay from 7th January, 1947, to 14th April, 1947, *ex-India*.

Major V. Srinivasan, Civil Surgeon, Nagpur, granted leave on average pay from 24th June, 1946, to 17th October, 1946, war concession leave on average pay from 18th October, 1946, to 17th December, 1946, and leave on half-average pay from 18th December, 1946, to 30th June, 1947.

PROMOTION

Lieutenant-Colonel L. K. Ledger, O.B.E., Inspector-General of Civil Hospitals, C. P. and Berar, is promoted to be 'Colonel' with seniority from 1st May, 1940.

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commission)

Lieutenant to be Captain

P. B. Johri. Dated 27th May, 1946.

RELINQUISHMENTS

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

Major W. G. Aranha. Dated 7th November, 1946.
Ty. Major E. K. P. K. Pillai. Dated 25th November, 1946.

Major I. R. Baziel. Dated 26th November, 1946.
Ty. Major Amarendra Nath Mukherjee. Dated 27th November, 1946.

Major Guruswami Audikesavalu Naidu. Dated 8th December, 1946.

Ty. Major A. H. Vatsyayana. Dated 26th December, 1946.

Major A. H. Akhtar, Medical Adviser (Pensions), D. A. D. M. S. (Pensions Branch), Defence Department, relinquished the appointment. Dated 3rd January, 1947.

The undermentioned officer relinquishes his commission on account of ill health :—

Captain P. N. Swift, dated 17th January, 1946, and is granted the honorary rank of Captain.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS
(Emergency Commissions)

Captain V. A. Mauskar. Dated 31st March, 1946.
Captain G. M. Diwan. Dated 6th May, 1946.
Captain R. S. Khanna. Dated 27th May, 1946.
Captain M. R. Reddy. Dated 13th August, 1946.
Captain T. V. Rao. Dated 30th September, 1946.
Captain S. B. Ghosh. Dated 16th October, 1946.
Captain S. L. Sawhney. Dated 16th October, 1946.
Captain N. K. Nag. Dated 26th November, 1946.
Captain S. K. Basu. Dated 29th November, 1946.
Captain S. K. H. Uraizy. Dated 2nd December, 1946.
Captain A. Bhattacharya. Dated 5th December, 1946.
Captain S. S. Sidhu. Dated 6th December, 1946.
Captain P. V. Kurian. Dated 7th December, 1946.
Captain C. T. G. K. Tilak. Dated 8th December, 1946.

Captain K. P. B. Menon. Dated 9th December, 1946.
Captain S. K. Mitra. Dated 11th December, 1946.
Captain G. Krishnaswamy. Dated 15th December, 1946.

Captain N. V. Gharpure. Dated 17th December, 1946.

Editorial Notice

VENEREAL DISEASES NUMBER

(Reprinted from November 1946 issue of *I.M.G.*, p. 483)

It is proposed to publish a special number, in October next year, on venereal diseases in India.

Original and special articles on their diagnosis, prevalence, complications and treatment will be welcome.

Contributions will be received up to July 1947 and placed before a special editorial committee.

It has been established gradually during the last 10 years or so that the venereal diseases do not thrive in India. Serious doubts have been cast on the previous estimates according to which 20 per cent of the population not showing any signs of syphilis consisted of latent cases of the disease. Such a state of things in India is impossible for a variety of reasons (*vide* this journal, vol. 81, 1946, nos. 6-7, p. 253). Contributions running counter to the old estimates need not therefore be held back in diffidence any longer.

Venereal diseases other than syphilis and gonorrhoea, some of them of special tropical interest, are very seldom discussed in the current medical literature in India. Recently they have been commented upon in this journal (vol. 81, 1946, no. 9, p. 365).

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

SOME OBSERVATIONS REGARDING THE TOXICITY OF THIAMIN CHLORIDE AND NICOTINIC ACID

By S. H. ZAIDI, M.D.

(From the Physiological Laboratory, K. G. Medical College, Lucknow)

WHILE working on the heart of *Rana tigrina* by the perfusion method recommended by Burridge (1935), I started with a fairly concentrated solution of pure synthetic thiamin chloride in concentration of one part in 1,000 of Ringer and watched the results. No sooner the drug was perfused than the heart, which had been beating normally so far, was suddenly arrested in diastole and remained as such throughout the period of drug perfusion. It, however, started beating strongly again when the Ringer was reperfused (see figure 1, plate VII).

The thiamin chloride solution was perfused at the arrow marked 10—³ B₁. The heart started slowing down and finally stopped in diastole as shown by the straight line on the tracing paper.

At the arrow 2/5R the perfusion of Ringer was started again. The vigour of each subsequent beats was powerful and the heart looked as if it had been infused with fresh vigour. The transitional inactivity of the heart, obviously enough, was not due to any damage done to the heart tissue, otherwise it would never have revived. The heart, so to say, went into a forced sleep and was neither dead nor damaged. Its energy was conserved instead of having been spent as happens in the case of seeds or the more familiar examples of spore-formation (see figure 2, plate VII).

The thiamin chloride solution was perfused at the arrows marked 10—³ B₁ and Ringer was perfused at the arrows R/10.

In these tracings perfusion of the concentrated solution of the drug thiamin chloride was alternated several times with Ringer R/10. The results are exactly similar to those of figure 1. In this particular case the strength of calcium in Ringer was reduced to one-tenth of the normal, this being an unbalanced Ringer (Burridge, 1935). A comparison of the results of figures 1 and 2 shows that calcium is not a factor in the arrest of the heart in diastole (Zaidi, 1946a).

Concluding remarks

This inactivity has been explained away as being due to acidity and hypertonicity by Boyd and Dingwall (1941), a view which in my opinion is erroneous for two reasons. Firstly, all acids have a damaging effect on the heart tissue as was proved by me by putting a drop of lactic acid in the reservoir of Ringer solution and the heart at once slowed down and was

evidently damaged. This heart could not be revived so easily as was the case with the one in question. This particular acid was selected to set at rest future criticism, if any; as lactic acid is both a weak acid and also a physiological product of bodily metabolism and hence is not foreign to the tissues.

To revive the heart after lactic acid perfusion was a very difficult task. It had to be neutralized with alkalis and treated with adrenaline; even then it only partially recovered. Besides, it showed cooked-meat appearance as described by Burridge (1935). Thus, the argument that the stoppage of the heart was due to acidity and hypertonicity is refuted in the light of what has been said. The concentrated solution of thiamin chloride though acid in reaction is not responsible for the stoppage as is apparent from its comparison with lactic acid. I have strong reasons to maintain that the action of the drug is not due to the acclaimed acidity but is an independent action of the drug itself. This being so, the concentrated solution of thiamin chloride is likely to be toxic to the heart.

So far thiamin chloride enjoyed a relative immunity against toxicity because the clinical use of vitamin B₁ is of very recent origin and besides there had been a worldwide deficiency of this particular vitamin. Deficiency cases are hardly the cases on which toxicity can be reached. The so-called massive doses in beri-beri hardly ever reach the concentration of one part in 1,000, where according to my observation, the toxic symptoms ought to supervene. Besides, if it was possible to push it to that extent in a beri-beri case and the heart were to stop due to high concentration of the drug, this sudden circulatory embarrassment would easily be explained away as being due to lack of vitamin B₁, rather than to the effects of the least suspected 'concentration' of thiamin chloride. The reason is that the literature is awfully poor in the observations on normal cases and abounds in deficiency cases only. When I first made a reference to this finding of mine before the K. G. Medical College Old Boys' Association, nobody present agreed with me that such a thing was possible. To ascribe to vitamin B₁ the rôle of toxicity appeared to be unjustified judging from the trend of opinion expressed then. Being handicapped by the limited supplies due to exigencies of war and also lack of funds it was not possible for me to show the results in animals on a large scale but I maintain that if glucose, a perfectly physiological product, could be toxic, if we exceed the optimum concentration, why not vitamin B₁? Besides, I pointed out to them that vitamin D has been shown to have certain poisonous effects if pushed lavishly and hyper-vitaminosis of vitamin D was an accomplished fact. Same was true for all the known hormones; why should thiamin be an exception? But the fact was hard for them to realize such

was the affection for B₁ at a time when the hospitals were flooded with patients of vitamin B₁ deficiency, both frank beri-beri and subclinical deficiency cases.

Next, I injected relatively large amounts of thiamin chloride in a frog and observed the effect. I took two similar frogs and injected 100 mg. of thiamin chloride in one frog (which henceforth would be referred as 'thiaminized' frog) subcutaneously under the abdominal skin and an equal amount of sterile distilled water into the other (the control). After about half an hour I found that the 'thiaminized' frog spread out its limbs. When turned upside down it did not make an attempt to correct its posture as was happening in the case of the 'control'. The reflexes were diminished to the point of being lost. The frog was left as such and after six hours its reflexes started coming back and gradually it was back to activity again after 8 hours or so (see figure 3, plate VII).

The ampoules supplied to me contained chlorobutanol 5 per cent as preservative and hence I endeavoured to obtain pure crystalline thiamin chloride. I did not succeed in my attempts in India and so I wrote to U.S.A. There too it was not possible to get pure crystalline stuff but Messrs. Eli Lilly and Co., Indianapolis, U.S.A., very kindly supplied me with a complementary sample of their Betalin S No. 395 which is not sent ordinarily to this country. This was solution of thiamin chloride in pure sterilized distilled water. I tried this on a new lot of frogs and I found the results exactly what they were previously. These tests confirmed our views held previously.

Sure (1939) observes that narcotized dogs show bradycardia and respiratory arrhythmia after receiving massive doses of vitamin B₁. Similar observations have also been reported by a good number of workers (Bicknell and Prescott, 1942).

To this account may be added my findings with nicotinic acid (Zaidi, 1946a). There too the concentrated solution was found to have had a toxic effect on the heart of frogs.

From the foregoing observations it is clear that vitamins do have a toxic effect and hypervitaminosis is possible in almost all vitamins. This may serve as a signal to the unwary clinicians, who having been accustomed to treat deficiency cases only, is likely to lose all sense of proportion and push the so-called harmless drugs to the points beyond the saturation limits and do harm. Since vitamins are powerful drugs their damaging properties ought to be as well defined and clear cut as are their recuperative actions.

The action of thiamin chloride on the alimentary system of the frog is again something that should be taken note of. In frog at least their action does not seem to be beneficial.

Schultze-Rhonhof and Paul (1939) have noticed that thiamin chloride has a depressant effect on the small intestine. While working

with the perfusion of heart (a slit in the ventricle's apex short circuits most of the perfusing fluid to bathe the outer wall of the heart allowing only some portion to enter the general circulation) through the aorta, I found certain very marked actions on the alimentary system. After a few hours' perfusion I noticed the tongue became very swollen and protruded, the intestines markedly increased in size, and the stomach became a huge dilated white sac (see figure 4, plate VII).

From this I conclude that thiamin has a detrimental action on the frog's alimentary system, a property which may not be shared by other animals. Nicotinic acid does not produce these effects and they must be held to be peculiar to thiamin.

Summary and Conclusions

1. Large doses of thiamin chloride exert a powerful toxic action on the heart of a frog.
2. Large doses of nicotinic acid have a similar action on the heart of a frog.
3. This injurious action of thiamin chloride is not due to the acidity of the solution but is an independent action of the drug.
4. Thiamin chloride exercises marked toxic effects on the alimentary system of the frog, a property not shared by nicotinic acid.
5. Application of these results to human beings is discussed.

I am deeply indebted to Professor W. Burrige for his sound advice, friendly criticism, and help in preparation of this paper. I am also grateful to Messrs. Eli Lilly and Co., Indianapolis, U.S.A., for the supply of their Betalin S No. 395.

THE GASTRIC MUCOSA IN TROPICAL MACROCYTIC ANÆMIA

REPORT OF A CASE

By J. C. PATEL, B.Sc., M.D. (Bom.), M.R.C.P. (Lond.), Ph.D. (Lond.)

(P. G. Singhance Hindu Hospital, Bombay) and

Y. M. BHENDE, M.D. (Bom.)

(Department of Pathology and Bacteriology, Gordhandas Sunderdas Medical College, Bombay)

FENWICK (1870) was apparently the first to comment on the structural alterations in the

stomach in Addisonian pernicious anæmia: there was thinning and pallor of the wall of the viscus, and microscopically, the secretory tubules were degenerative and atrophic with collections of lymphocytes round them. Cahn and von Mehring (1886) drew attention to the absence of free hydrochloric acid in the gastric juice in Addisonian pernicious anæmia and Faber (1926), studying properly fixed material (Faber and Bloch, 1899), came to the conclusions—(1) that this achylia (= anacidity) was always exogenous in origin, (2) that it was an expression of gastritis 'which is not superficial catarrhal inflammation' but 'a disease of the whole gastric parenchyma in analogy with nephritis and hepatitis' and (3) that achylia may exist without any structural alterations in the gastric mucosa.

The classical work of Castle and his associates (1929, 1930, 1931) demonstrated that Addisonian pernicious anæmia was due to the lack of the intrinsic factor in the gastric juice and established the supreme rôle of the stomach in the pathogenesis of this anæmia. Magnus and Ungley (1938) found that the basic lesion in stomach in Addisonian pernicious anæmia was a non-inflammatory atrophy of all its coats in its upper two-thirds, either due to endocrinal or nutritional deficiency, or possibly congenital in origin. On the other hand, Brown (1934), Jones, Benedict and Hampton (1935) and Meulengracht (1939) believed that, histologically, the atrophic lesion was an expression of diffuse gastritis as originally suggested by Faber (1926). Jacobson (1939) claimed that the most significant lesion in the gastro-intestinal tract in Addisonian pernicious anæmia was the almost complete absence of the argentaffine cells, cells whose normal distribution paralleled the localization of the anti-anæmic principle in the alimentary canal in both man and pig. Fox and Castle (1942) have proved that the site of secretion of the intrinsic factor, as defined by the hæmopoietic activity of the human stomach preparations, corresponded to the site of degenerative processes in the stomach (the fundus and the cardia, but not the pylorus or the duodenum) in Addisonian pernicious anæmia.

The lack of the intrinsic factor of Castle responsible for Addisonian pernicious anæmia, therefore, has an underlying structural basis—an atrophy of the acid-secreting area of the stomach, which is also the site of secretion of the human intrinsic factor. On the other hand, absence of the extrinsic factor(s) in the diet is the prime ætiological factor in tropical macrocytic anæmia(s). In the majority of the cases of the latter, though not in all (Bhende, 1942; Bhende and Patel, 1946), there is no histamine-fast achlorhydria or true anacidity. On *a priori* grounds, in this type of macrocytic anæmia, the stomach should not show structural alterations similar to those of Addisonian pernicious anæmia. Though a few cases, apparently of tropical macrocytic anæmia, have been studied at the

autopsy (Balfour, 1927; Mitra, 1931; Gupta, 1932), there are no recorded observations on the appearance of the gastric mucosa in this variety of macrocytic anæmia. In 'the pernicious anæmia of pregnancy', Callender (1944) found the gastric mucosa normal; there was neither atrophy nor inflammatory change. The report of the study of even a single proven case of tropical macrocytic anæmia would seem to be of some interest.

Case report

(I, 363/39) A Hindu male, aged 55, was admitted to the P. G. Singhanee Hindu Hospital for—(i) vague pains in the epigastrium—duration two years, (ii) general weakness—duration one year, (iii) low irregular fever—duration one year, (iv) pigmentation of the face, hands and feet—duration six months, and (v) vomiting—duration two days. There was nothing to note in the family history. He earned his livelihood as a petty shop-assistant. Nothing significant could be elicited about any illnesses in his childhood. There was no history of any attacks of stomatitis, diarrhœa or malaria. He subsisted on a poor vegetarian diet.

Examination showed a man of average build but poorly nourished. Temperature 97.6°F.; pulse 72; respirations 18. There was pallor of the skin and the mucosæ and brownish pigmentation over the forehead and the dorsum of the hands and feet. There was no œdema of the ankles. The tongue was pale and flabby. The liver and spleen were not palpable; there was no evidence of any free fluid in the peritoneal cavity. The abdomen was not tender in any region. The lungs appeared normal. The heart was normal in size and no hæmic murmur could be heard. The B.P. was 110/70. The nervous system appeared intact; all the extremities showed normal sensations and reflexes. There was no paræsthesia.

Laboratory investigations.—(i) Blood: hæmoglobin 7.3 gm. per 100 c.cm.; erythrocytes 1.56 millions per c.mm.; leucocytes 3,500 per cent; monocytes 2 per cent and lymphocytes 61 per cent; cell volume 18.6 per cent; mean corpuscular volume 124 (Bhende and Patel, 1946); mean corpuscular hæmoglobin 47 micro-micrograms; mean corpuscular hæmoglobin concentration (corrected to cell volume 42 = 100 per cent) 38.3 per cent; colour index (corrected to 14.5 gm. of Hb. = 100 per cent) 1.4; volume index 1.24; saturation index 1.12. The smear showed anisocytosis and poikilocytosis but there were no nucleated red cells or parasites. The van den Bergh reaction was negative both direct and indirect; the icteric index measured 5 units. The Kahn flocculation test was negative. The blood urea was 67.5 mg. per cent.

(ii) *Urine and fæces.*—Beyond a trace of albumin there was no abnormality in the urine. The fæces did not give a positive test for occult blood, and no ova, cysts or parasites could be found.

(iii) *Gastric analysis*.—With the oat meal, the fractional method showed absence of free hydrochloric acid in all the samples and a low total acidity. Two days after the test was repeated using 50 c.cm. of 7 per cent alcohol as the test meal and 0.5 ing. of histamine as the optimum stimulus, this showed the presence of free acid in all the three samples aspirated after the injection.

(iv) *Myelogram*.—The sternal puncture smear preparation gave the following differential count of one thousand nucleated cells:—

		Per cent
A. The leucocyte series:—		
Neutrophils segmented	..	4.50
Neutrophils stab	..	6.50
Neutrophils juvenile	..	1.20
Myelocytes	..	5.60
Premyelocytes	..	1.00
Myeloblasts	..	0.20
Eosinophils	..	0.50
Basophils	..	0.20
Monocytes	..	0.70
Lymphocytes	..	22.20
B. The red cell series:—		
Proerythroblasts	..	3.8
Megaloblasts	..	2.5
Megaloblast hæmoglobinized	..	0.3
Normoblasts	..	50.8

The terminology employed is that of Israels (1939, 1941). Other significant features of the smear were the presence of giant premyelocytes, hypersegmented neutrophils and the absence of any mitotic cells among the red cell series. The peroxidase count of the white cell series showed 22 per cent were peroxidase-positive and 78 per cent were peroxidase-negative.

Radiological investigations showed a funnel-shaped stomach with poor peristalsis and quick emptying. There was no niche or filling defect.

Progress in the wards.—He was diagnosed as a case of tropical macrocytic anaemia and put on an acid-hydrochloric (dilute) mixture with meals and intramuscular injections of Exatrope (Glaxo), crude liver extract, 4 c.cm. daily for fourteen days. No iron was administered. On the 8th day of this treatment, the reticulocyte count was 23.8 per cent and, on the 20th day, the blood count was: hæmoglobin 11.07 gm. per 100 c.cm.; erythrocytes: 2.52 millions per c.mm.; leucocytes: 6,800 per c.mm.; differential count: neutrophils 35.5 per cent; eosinophils 0.5 per cent; monocytes 4.5 per cent; and lymphocytes 59.5 per cent; cell volume 30.5 per cent; mean corpuscular volume 121μ (Bhende and Patel, 1946); mean corpuscular hæmoglobin 35.9 micro-micrograms; mean corpuscular hæmoglobin concentration 29.6 per cent; colour index 1.2; volume index 1.2; saturation index 1.0. He developed oedema of the ankles during the first few days of the treatment but this disappeared quickly. The general condition, by this time, had improved very much and the pigmentation on the forehead had disappeared completely, though it persisted faintly on the hands and the feet. He was discharged after twenty-four days'

hospitalization and asked to attend the out-patient department. Here he was prescribed a good diet and hydrochloric acid dilute mixture. Liver extract was stopped. After about one month on this regime his abdominal discomfort reappeared and he also complained of eructations. Fifteen days later he had an attack of glossitis and contracted bronchitis. He was advised readmission to the wards; this he refused and continued on the acid-mixture alone for three months.

Second admission.—This was about four months after his discharge. At this time he complained of general weakness, loss of appetite and paræsthesia in all the extremities. Examination showed marked brown pigmentation of the forehead and the dorsum of the hands and feet. The tongue was pale and glossy, but only slightly painful. Examination of the lungs showed signs of bronchitis. There was no hæmic murmur in the heart. In the extremities the sensations and reflexes were normal. The blood count showed hæmoglobin 8.13 gm. per 100 c.cm.; erythrocytes 2.0 millions per c.mm. and leucocytes 5,400 per c.mm. Intramuscular crude liver extract therapy in large doses was started immediately, but his condition worsened and he expired on the 10th day of admission.

Autopsy record.—A partial post-mortem examination was performed soon after death: no autodigestion of the stomach was noticed. The significant findings were as follows: The liver was enlarged and pale, but naked eye, no fatty change could be seen. Histologically, the liver cells showed cloudy change; there was no hæmosiderosis. The spleen was normal in size and somewhat pale on the cut surface. Histologically, the capsule appeared thickened, the trabeculae were prominent, and the arterioles showed hyalinization. The lymphoid tissue of the organ was atrophic. There was moderate hyperplasia of the reticulo-endothelial cells of the pulp. No malarial pigment could be detected nor could any hæmosiderin be demonstrated. There was no evidence of hæmopoiesis in the organ. The kidneys were pale, but no fatty change was evident. Histologically, a few of the glomeruli were hyalinized. The tubular epithelium showed the changes of cloudy degeneration. At some places the proximal convoluted tubular epithelium was flattened and the tubular lumina contained an eosinophilic fluid. The blood vessels showed the changes of arteriosclerosis.

The stomach.—Naked eye, the viscus was normal in size. Externally there was nothing to note. On opening no ulceration or growth could be detected. The walls appeared to be normal thickness, the mucosa was pale but the mucosal folds and rugae showed the normal pattern all over. For the histopathological study the organ was stretched and fixed; representative portions from the cardia, the fundus, the body, and the pylorus were sectioned. Only the hæmatoxylin and eosin stains were employed.

The cardia (figure 1, plate VIII).—The surface epithelium was normal. The crypts appeared widened. The glands were less dense than normally, but there was no distortion of the glandular architecture. The lamina propria did not show any increased connective tissue but the cellular content was larger than normal. The cells were mainly lymphocytes with only a few plasma cells. At one place was found a polypoidal hypertrophy of the mucosa and in this the glands showed cystic dilatation. The submucosa was widened and showed small collections of lymphocytes and plasma cells round the capillaries. The rest of the coats were unaltered.

The fundus and the body (figure 2, plate VIII).—The surface epithelium was normal. There was widening and shortening of the crypts. No appreciable diminution in the glandular content could be made out nor was there any irregular branching or tortuosity of the glands. As far as could be judged the two specific types of epithelial cells—the chief or zymogenic cells and the oxyntic or parietal cells—were present in normal numbers but in the necks of the glands the mucous cells were on the increase. The interstitial tissue of the lamina propria was definitely increased mainly due to the large accumulations of lymphocytes and plasma cells. No aggregations into lymphoid follicles could be made out. A few eosinophils could be identified, as also an occasional Russell's body. The submucosa showed the same features as in the region of the cardia. The other coats did not show any changes.

The pylorus (figures 3 and 4, plate VIII).—The surface epithelium was well preserved. The crypts were conspicuously wide. The glandular content compared well with the normal. Only an occasional gland showed distortion and cystic changes. In a single instance, out of the six blocks studied, was detected an islet of typical intestinal epithelium (figure 4). The interstitial tissue was markedly increased and in this both the connective tissue and the inflammatory cells seemed to share. The cells were mainly plasma cells, next came the lymphocytes, and at places they formed focal accumulations. Prominent lymphoid follicles with germinal centres could also be made out here and there. Eosinophils were fewer. Russell's bodies were many more than in the other portions of the stomach. The cellular infiltration was much more at the surface than in the deeper portions of the lamina propria. The submucosa again appeared widened and showed oedema and small accumulations of lymphocytes and plasma cells. The other coats did not show any changes.

Discussion

The patient was emaciated and clinically did not show any signs of cord involvement. The hæmatological studies revealed the presence of a macrocytic normochromic anæmia. The absence of a positive van den Bergh reaction and the presence of free hydrochloric acid in the gastric

juice after histamine stimulation were points against the diagnosis of Addisonian pernicious anæmia. The myelogram, from our experience, was compatible with the diagnosis of tropical macrocytic anæmia. The clinical and laboratory findings put together, therefore, entertained no other diagnosis.

Histologically, the stomach showed the condition of chronic gastritis: a diminution in the parenchymatous elements of the mucosa, fibrosis and presence of chronic inflammatory cellular accumulations in the mucosa and the submucosa. These findings resemble, to some extent, those described for Addisonian pernicious anæmia by Faber (1926), Brown (1934), Jones, Benedict and Hampton (1935) and Meulengracht (1939), though atrophy of the secretory elements was not marked. They are, however, in direct contrast to those of Magnus and Ungley (1938). The local polypoidal condition in our case has also been described in Addisonian pernicious anæmia (Olson and Heck, 1945).

Ætiologically, Addisonian pernicious anæmia and tropical macrocytic anæmia are different, in some ways contrasting entities. Lack of the intrinsic factor is the cause of the former; this is a strong basis for the existence of a specific lesion in the gastric mucosa which actually secretes that factor. On the other hand, the lack of all exogenous extrinsic factor responsible for tropical macrocytic anæmia may not (? need not) produce specific structural alteration in the stomach. Only if the changes of non-inflammatory atrophy of the gastric mucosa described by Magnus and Ungley (1938) be universally accepted as the underlying structural basis responsible for the absence of the intrinsic factor of Castle in Addisonian pernicious anæmia, will the changes described by us for tropical macrocytic anæmia have any meaning at all. It is possible that with the recent discovery of the efficacy of 'folic acid' in the treatment of both these types of anæmias their pathogenesis may have to be reviewed. We need hardly add that, though the opportunities to study cases of tropical macrocytic anæmia at the autopsy will continue to be rare and rarer day by day, it would be folly to draw any conclusions from the study of a single case.

Summary

The changes in the gastric mucosa in a single proven case of tropical macrocytic anæmia are described.

A STUDY ON CLINICAL VALUE OF THE WIDAL REACTION AND ITS VARIATIONS IN TYPHOID FEVER

By K. U. JHATAKIA, M.D.

Honorary Assistant Physician, Sir J. J. Hospital, Tutor in Medicine, Grant Medical College, and Research Worker, Sir H. N. Hospital, Bombay

THIS problem formed a part of the research work carried out on 'Study of prolonged pyrexia cases' at Sir H. N. Hospital, Bombay. It is a fact that in general practice most of the cases are diagnosed as typhoid on the strength of Widal reaction alone, and other methods are rarely resorted to. This stresses the value of the Widal reaction in clinical medicine as far as diagnosis and prognosis are concerned. At present we do not know much about the significance of its variations and fluctuations met with during the course of the illness. I do not intend to discuss the serological aspects of this test and factors influencing it, but I will reproduce my findings on this study about its clinical value.

Seventy-five cases of typhoid fever were studied in detail. Clinical, bacteriological, serological and therapeutic study was carried out. Widal reaction, blood, urine and stool cultures and examinations were done once every week throughout the illness. These patients were examined clinically every day. In this paper I intend to present only the findings on 'Widal reaction test' and conclusions drawn from this.

There are many queries arising about this test. Many questions are put by students, undergraduates and post-graduates. Answers to these

questions are not always easy. Some of the queries are as follows:—

1. What titres in Widal test should be considered as absolutely diagnostic for typhoid fever?

2. What modifications occur in titres if a patient is previously inoculated with T.A.B.?

3. Which agglutinin is more diagnostic, 'O' or 'H', and what are their individual significance and value?

4. Do the titres of 'O' and 'H' agglutinins vary or fluctuate in subsequent weeks? If so, do they undergo similar fluctuation or independent of one another? If such variations occur, what is their clinical significance?

5. Are these variations, fluctuations, etc., of any value in forecasting the course of the disease, and prognosis in a patient?

6. Is it possible for the agglutinins not to appear at all in blood, in spite of patient being a proved typhoid case, bacteriologically?

Interpretations of the agglutination test on which we chiefly rely for diagnosis are by no means clearly understood. Many factors influence this reaction but we have no precise idea about them. Some facts gathered from present literature are briefly reviewed here.

Widal reaction becomes positive usually after an illness of 10 days, but 20 per cent of cases may show positive agglutination in the first week. Then the titre gradually rises and agglutinins are found in 90 per cent of cases in the 4th week of illness and persist for some weeks thereafter.

Detection of 'O' agglutinins is a valuable and often necessary step in the diagnosis of enteric infection, but it is of less value in differentiating between one type of enteric infection and another.

Problem of diagnosis in inoculated persons with T.A.B. is often difficult. 'H' agglutinin titres developed due to inoculations are higher than 'O' agglutinin titres and secondly 'H' agglutinins persist longer than 'O' agglutinins. Thus 'O' agglutinins are of more significance than 'H' agglutinins in inoculated persons. In an inoculated person a high 'H' agglutinin titre (1:50 to 1:250) by itself unless rising (from 1:50 to 1:250) is of no significance. No doubt, we will have to consider the possibility of non-specific stimulation of antibody production. This shows that a diagnosis of enteric fever can be based with reasonable safety on a single agglutination test only if a high titre of 'H' agglutinins is found in an uninoculated person or a very high titre in person who is not very recently inoculated or an 'O' titre well above the normal level in the uninoculated or not very recently inoculated person.

In interpreting the results of agglutination titres, one has to consider the stage in disease at which the sample of blood has been taken and the previous inoculation with T.A.B. vaccine. No arbitrary titre can be selected at or above which an agglutination can be regarded as positive in diagnostic sense and below which it can be regarded as negative, but should be

viewed along with other evidences present. In majority of typhoid cases during the third week of illness, 'H' titre goes well above 1:100 and 'O' titre also over 1:100. 'The rise in agglutinins is associated with a decreasing bacteremia and the time at which the agglutinin titres reach maximum coincides approximately with an amelioration in the patient's general condition as indicated by a gradual fall in temperature' (Topley and Wilson, 1944), but this is not always so, as shown in my cases.

'Agglutinins usually appear in blood between 3rd and 7th day of disease, rise first slowly, then more steeply to a maximum between 16th and 22nd day and then fall at first steeply, later very slowly, so that they are detectable for weeks or months after convalescence' (Topley

and Wilson, 1944), but this is also not true in all cases as shown later on in this paper.

A few observations were made on the various types of fluctuations in agglutinin titres during the course of illness. Titres did not always rise uniformly in subsequent weeks and so gave rise to various types of fluctuations. Rise and fall of individual titres of 'O' and 'H' agglutinins also varied widely. Looking at the results, I have divided these cases into two main groups:

(a) Cases in which agglutinin titre goes on rising gradually during acute illness. This is a common finding.

(b) Cases where fluctuations and variations in titres in subsequent weeks are noted.

Thirty-six per cent cases had uniformly usual rise in titres. Mortality in this group was 19

per cent. 64 per cent cases belonged to group b. Mortality in this group was 20 per cent.

Gradual rise in successive weeks and then gradual fall in titre with recovery is a known

fact. This should be so in the majority of cases, but in our series this was observed in only 36 per cent cases, while rest showed variations from usual findings. These variations were not

same for 'O' and 'H' agglutinins. Significance of these fluctuations is not so clear and rather difficult to understand. The method, suspensions, chemicals and persons concerned in carrying out the test were the same throughout. Sometimes agglutination test becomes even negative during phase of acute illness and then again becomes positive later on. The findings in a few cases are shown in table I. It will be seen from this table how the titres vary in successive weeks. None of the patients had previous T.A.B. inoculation.

In all these, last reading was taken a week after the temperature had touched and remained normal. In some cases 'H' agglutinins alone were present while in others 'O' agglutinins alone were found. In yet others, either both these agglutinins were present or absent. The findings were as follows :—

(i) 'H' agglutinins alone—In 21 per cent cases there were only 'H' agglutinins and, no 'O' agglutinins were detected throughout the illness. Blood cultures in all were negative and there was no history of inoculation with T.A.B. in any one. Titre of 'H' agglutinins did not rise above 1:150 in those four patients who died and in all the rest who survived titre went beyond 1:150 in subsequent weeks. This shows that rise in 'H' agglutinins in subsequent weeks forecasts a better prognosis. This is applicable where 'H' agglutinins alone are present in the blood.

(ii) 'O' agglutinins alone—In 12 per cent cases only 'O' agglutinins appeared, out of which one patient died. No definite conclusion could be drawn from the findings.

(iii) No agglutinins at all—In two cases no agglutinins were detected in the blood throughout the illness, while blood culture was positive for *B. typhosus* during 2nd week. One patient was very toxic from the beginning of the illness and died later while the other survived.

(iv) Both 'O' and 'H' agglutinins were detected in remaining 64 per cent cases. These agglutinins showed many fluctuations and variations in subsequent weeks. These variations were observed and studied in detail, as the test was repeated once every week throughout the illness of the patient. As stated before various types of fluctuations were met with 'O' and 'H' agglutinins.

Significance of either rise or fall of respective agglutinins at various stages and under various conditions is not so well understood. Bhatnagar (1944) observed that "O" titre rises in toxic type of cases and a considerable fall of "O" titre in serum *always preceded recovery*. So persistent high rise of "O" agglutinins must be regarded as pathological. My findings agree with the first part of the above statement but not with the second part. Number of cases in my series is too small to form any definite opinion or inference, and so I will reproduce my findings on these variations in titres in table II.

This table also shows the different types of fluctuations.

1. In some cases, neither 'H' nor 'O' agglutinins appear in the serum throughout the illness of the patient. Blood culture in such cases is usually positive.

2. In some cases, either 'H' agglutinins or 'O' agglutinins alone appear in the serum. In cases of 'H' agglutinins alone, if titre remains below 1:150 even in subsequent weeks, outlook of the patient is not good.

3. Those cases in which 'O' titre gradually falls in subsequent weeks from initial high titre do quite well. This concurs with Dr. Bhatnagar's observation that a considerable fall of 'O' titre of serum always preceded recovery.

4. But corollary of this observation is not always true, as in my work I observed 'O' titre rising gradually from initial lower titre in 13 cases and titre did not fall at all even with clinical improvement of these cases; so high persistent 'O' titre is *not always* to be considered as a bad prognostic sign.

5. It is believed that titres usually rise in successive weeks if patient is showing good resistance, but in 5 cases 'O' titre remained constantly at low level. One out of these five died. This persistent low titre throughout illness cannot be taken as a bad sign in all.

6. Variations of 'H' agglutinins and of 'O' agglutinins are many and it is difficult to draw any definite conclusion from them. All these fluctuations are tabulated in table II. One observation needs a mention. Rising of 'O' agglutinins titre and falling of 'H' agglutinins titre in successive weeks is a bad sign. This was observed in 3 cases and all died.

I thank the authorities of Sir H. N. Hospital, Bombay, for the kind permission to publish this article and Dr. T. C. Kaji, M.B., B.S., who was associated with me in carrying out this study.

STIBANATE (SODIUM ANTIMONY GLUCONATE) WITH PEDUNCULINE IN THE TREATMENT OF KALA-AZAR

By SUBODH CHANDRA SANYAL, B.Sc., M.B.
 (Natore, Rajshahi District)

THE beneficial effects of the use of Pedunculine Pentavalent Antimony Gluconate Compound in a series of fifty cases encourages me to publish the following detailed record of twelve cases in the belief that the introduction of this new preparation will mark a great advance. The patients treated by this new preparation had no

tendency to relapse during an observation period of six months. An immediate response was seen in the rapid fall of temperature, disappearance of the parasites, improvement in the blood, and decrease in the size of liver and spleen. Only six injections were required to complete the course of treatment, whereas, in the control cases, twelve or even more injections were required to have similar improvement in blood and diminution of spleen and liver. All the injections were given intramuscularly on every alternate day. The adult dose is as follows :—

1st week	Stibanate 2 c.c.	I.M. combined. Every alternate day 3 such.
	Pedunculine 3 c.c.	
2nd week	Stibanate 4 c.c.	I.M. combined. Every alternate day 3 such.
	Pedunculine 3 c.c.	

Together with this some liver extract orally was prescribed to combat anaemia.

From the table, I come to the conclusion that in almost all the cases the temperature became normal after the 3rd injection and the aldehyde-test and Chopra-test became negative after the six injections. The addition of Pedunculine to the pentavalent antimony gluconate (stibanate) gives a synergistic action to the antimony salt.

I offer my thanks to Mr. B. P. Dalmia of North Bengal Sugar Mills Ltd., Gopalpur, for giving me facilities to work in his Charitable Dispensary and to Dr. Prahlad Chandra Bysak, L.M.F., for examining the blood of the patients.

N.B.—Stibanate and Pedunculine are available at Gluconate Ltd., Calcutta (135, Prinsep Street), Calcutta.

Table showing the record of cases

Serial number	Sex	Age	A. T. and C. T.	Number of injections	Conditions of cases	REMARKS
1	M., M.	40	+++	6	Relapse after 3 years	Temperature became normal on the 2nd injection. Epistaxis stopped, spleen liver diminished in size after 6 injections. Blood negative.
2	H., M.	9	++	6	New case, suffering 1 year.	Temperature became normal on the 3rd injection, spleen liver diminished in size. Blood negative.
3	H., M.	40	Doubtful	6	Four months suffering	Temperature dropped on the 1st injection. Spleen liver diminished in size. Blood negative.
4	M., F.	8	+++	6	Suffering for 1 year with canerum oris.	Temperature dropped after 4 injections. Canerum oris improved. Blood negative.
5	M., M.	11	+++	4	Suffering for 1 year indolent ulcer, left leg.	Died after 4 injections.
6	H., F.	35	+	6	Two months suffering	Temperature became normal after 3rd injection. Blood negative after 6 injections.
7	H., M.	12	Doubtful	6	Suffering for 5 months	Temperature became normal after 2nd injection. Spleen liver diminished in size. Blood negative after 6 injections.
8	M., F.	28	+++	6	Suffering 1 year. 16 pentavalent antimony I.V., no result.	On 3rd injection temperature continued normal. Blood negative after 6 injections.
9	M., M.	32	+++	6	Nine months suffering. Antimony intolerance.	Tolerated this preparation nicely. Temperature dropped in 2nd injection. Spleen liver diminished in size. Blood negative.
10	H., M.	26	+++	6	Antimony resistant. I.V. 12 injections, no result.	On the 3rd injection temperature dropped and continued normal. Blood negative after 6 injections.
11	H., M.	12	++	6	Relapse after 1 year	Temperature normal on the 2nd injection. Spleen liver diminished in size. Blood negative after 6 injections.
12	M., M.	20	+++	6	New case for 6 months	Temperature dropped on the 3rd injection and continued normal. Spleen liver diminished in size. Blood negative after 6 injections.

THE INCIDENCE AND CAUSATION OF GLYCOSURIA IN PREGNANCY.*

Part I

By K. C. BATLIWALLA

Department of Physiology, Seth G. S. Medical College, Parel, Bombay 12

DURING the last two decades notable progress has been made in the knowledge of glycosuria in general and glycosuria during pregnancy in particular. It is realized nevertheless that this knowledge is far from being complete. However, adequate methods for the routine diagnosis and successful control of glycosuria during pregnancy have been found and developed so that advantage may be taken of them in the treatment of this condition.

Important and useful information on the aetiology of glycosuria has come at different times through a number of investigators and through improved methods of technique and advanced knowledge of anatomy, physiology, pathology as well as other sciences, particularly organic and biochemistry.

The glycosuria in pregnancy is however a problem of more recent investigation. Cammidge (1913) considered the sugar present in urine during the later months of pregnancy to be chiefly lactose but from further works by Joslin, Lawrence, Shir, Edward Allen, W. J. Dieckmann, Priscilla White, Addressi and others, it has been definitely established that the sugar so persistently present in urine during pregnancy is glucose and not lactose as was at one time supposed. Lactosuria in pregnancy according to Joslin (1935) is rare and according to him the incidence of glycosuria in pregnancy is increased when the pituitary prolactin of the blood is high.

Addressi (1936) opines that the threshold for glucose is lowered during pregnancy. This he believes is due to the increased tonus of the segment which innervates the kidney.

Lawrence (1939) in his book 'The Diabetic Life' says that temporary renal glycosuria is common in pregnancy after the 5th month. According to Shir (1939) alimentary and renal glycosuria are prone to develop after the middle of pregnancy and complicate the treatment of diabetes, when present.

Allen (1939) states the enlargement of the foetus (which is a common feature in diabetic cases) was noted even in non-diabetic glycosuria cases.

Lawrence (1940) stated that 'pregnancy often produced a temporary lowering of the renal threshold of glucose. It is common both in diabetics and non-diabetics. It is perhaps due

to an effect of changed pituitary activity or changed kidney function. The cause of this lowered threshold is still obscure'.

There is thus a divergence of opinion with regard to the causation of glycosuria during pregnancy. The cause of it is still obscure as has been well emphasized by Lawrence. Under these circumstances an investigation on the incidence and causation of glycosuria in pregnancy was undertaken.

Experimental

The experimental work on pregnant women was carried out on the out-patients attending antenatal clinic of the Nowrojee Wadia Maternity Hospital, Bombay, and on the in-patients attending the antenatal ward of that hospital. Investigation was also carried out on the out-patients of the Hospital for Women and Children, Tardeo, Bombay. The cases were selected exclusively from the free patients of the poor class attending these hospitals with the idea of getting a full co-operation in the conduct of the enquiry.

In all 540 cases were examined. Detailed history of each was taken. Particular attention was paid in noting the quality and quantity of diet of each patient. Specimen urine of each case was arranged to be collected 3 hours after the normal midday meal. Examination of the urine was made at the Biochemistry Laboratory of the Seth G. S. Medical College, Bombay. As this institution is opposite the Maternity Hospital, very little interval elapsed between the passing and examination of the urine. The urine was mainly tested for glucose and other abnormal constituents such as albumin, indican, lactose and acetone bodies. In order to differentiate between glucose and lactose fermentation, osazone tests were performed. Results are shown in the table and in graphs I to V.

Discussion

The incidence of glycosuria in the later months of pregnancy is higher and shows a gradual increase in graph I. The incidence of glycosuria among vegetarians and non-vegetarians is shown

Graph I.

Incidence of Glycosuria in different months.

*The papers that are intended to be published under this head form the subject-matter of a thesis approved for the Ph.D. degree of the Bombay University. The work reported herein was done under the guidance of Professor S. P. Niyogi in the Physiology Department of the Seth G. S. Medical College, Bombay.

TABLE

Showing incidence of glycosuria and other abnormalities in different months of pregnancy

Month	CASES			PER CENT INCIDENCE OF GLYCOSURIA								OTHER ABNORMALITIES			
	Total	Vegetarian	Non-vegetarian	Total	Vegetarian	Non-vegetarian	Calcium		Vitamin C		Lactose	Albumin	Acetone	Indican	
							Rich	Poor	Rich	Poor					
3	25	6	19	4.0	1	
4	29	11	18	6.9	1	..	1	
5	76	47	29	13.1	14.7	11.9	10.8	15.4	3.7	18.3	..	3	15	..	
6	90	28	62	20.1	23.1	17.7	18.1	22.4	5.0	24.3	..	4	9	2	
7	126	77	49	20.0	30.3	29.1	29.0	31.0	6.4	38.0	..	6	22	..	
8	114	57	57	35.2	36.8	33.3	32.2	38.4	8.3	42.2	..	2	24	4	
9	80	42	38	37.5	37.2	35.9	33.0	40.0	13.0	49.1	4	9	13	3	

in graph II. It will be seen that there is some difference in incidence between vegetarians and non-vegetarians.

It must however be noted that the so-called non-vegetarians of poorer class of people in Western India take too little of animal diet per day. Those who take even 1 oz. of animal diet (meat or fish) per day (a very small quantity compared to the Western or European standards) have been classed as non-vegetarians. Otherwise, there would have been a greater difference in the incidence of glycosuria between the vegetarians and the non-vegetarians.

Among the poor section there are some whose cereal food consists mainly of rice and there are others who take wheat, millets, etc., in addition. Incidentally it was found that calcium rich food and calcium poor food made a difference. The incidence of glycosuria in cases taking a calcium poor cereal and calcium rich cereal is shown in graph III.

The difference is all the more marked from the 7th month onwards. According to Swanson and Job (1939) the mineral intake, especially of calcium, gradually increases in a foetus from

Graph III.

Graph IV.

Graph V.

month to month from the 5th month onwards. Winkler and Fritsche (1939) have found the concentration of calcium in the foetal tissue to run parallel with the advancement of pregnancy. Thus, as the foetal demand increases there is a tendency to a decrease of calcium in the maternal blood unless an adequate calcium rich diet is taken.

Effect of vitamin C content of the diet is interesting. The incidence of glycosuria in cases consuming a vitamin C rich food is lower as compared to cases taking a vitamin C poor diet. The difference is seen in graph IV.

Fruits are taken as articles of diet rich in vitamin C and a pregnant woman who took one sweet lime (*Citrus medica* var. acid) or an orange (*Citrus aurantium*) or any other fruit containing an equivalent of over 50 mg. of vitamin C per day was classified as a case taking vitamin C rich diet.

It is true that fresh leafy vegetables are very rich in vitamin C, but the people of Bombay hardly get them fresh. Besides, the bulk of vitamin C in vegetables is destroyed in cooking. Frying and even boiling in the presence of plenty of oxygen (as is done by the poorer classes of people in Western India) lead to rapid and almost complete destruction of vitamin C. In graph V is shown the incidence of glycosuria in primipara, bipara, etc.

Summary

1. The reducing sugar so often found in the urine of pregnant woman is usually glucose. It is not lactose. The latter is not found until the 9th month of pregnancy and that too a few days before the onset of labour and its percentage is very small.

2. The incidence of glycosuria shows a gradual and a definite rise from month to month, as pregnancy advances.

3. The incidence is greater in the vegetarians than in the non-vegetarians.

4. This incidence is greater in cases taking calcium poor diet than in those taking calcium rich diet and the difference in this incidence is more pronounced in the last two months of pregnancy.

5. This incidence is far greater in cases taking a diet poor in vitamin C than in those taking a diet rich in this ingredient. The difference in this incidence becomes all the more pronounced in the last months of pregnancy.

6. This incidence is greater in subsequent pregnancies, i.e. the least in primipara, a little more in bipara, still more in third para and so on.

PARENTERAL QUINACRINE IN MALARIAL FEVERS

By K. L. BASUMULLICK

(Ludlow Jute Mills)

and

J. C. GUPTA

(School of Tropical Medicine)

THE cases reported in this article were treated in the medical department of the Ludlow Jute Mills situated in village Chengail in the Howrah district. The village is situated on the north bank of river Hooghly about 17 miles from Calcutta. The patients were mainly the labour force employed by the Ludlow Jute Mills and Press, resident partly on company-owned premises and partly in the nearby villages. A small percentage was from among the dependants of the employees.

Table I shows the normal incidence of malarial fevers as well as the epidemic incidence during 1944-45.

TABLE I

All malaria cases (acute attacks and relapses)

Cases per 1,000 p.m.	18.15	14.5	23.8	53.2	117.7

It will appear from table I that the incidence of malarial fevers suddenly began to rise in July 1944 at a time when quinine had become rather difficult to obtain and injectable form of quinine had become unavailable.

Our reason for using parenteral quinacrine

From July 1944 to September 1944 we used quinacrine tablets orally in the ordinary manner, namely, one tablet three times a day after meals for 5 days. We found that it took 3 or 4 days for the temperature to become normal and these 3 or 4 days of fever rendered the patient weak enough to require another 3 or 4 days to recoup sufficient strength to come back to mill work. In this series there were 824 cases of which 16.4 per cent had relapsed after a mean afebrile period of 17 days. The average number of days when the patient could not resume duties was 7 and the average loss of wages to the workman was for one week. As the epidemic was assuming severe proportions the man-hours lost were fast becoming a problem from the point of view of stoppage of production. Then again pernicious types of malaria had made its appearance. Its incidence was 4.1 per cent of all malaria cases. The third factor was the high incidence of chronic gastritis among the labouring classes brought on by poor and constantly changing quality and adulteration of the foodstuff and all the sequences of the famine of 1943. Considering all these factors we started the injection of quinacrine solution from the month of October 1944.

Preparation of the solution.—Quinacrine hydrochloride is soluble in 1 in 30 of water so that one tablet is soluble in 3 c.c.

Nine hundred tablets were dissolved in 2,700 c.c. of distilled water in a tall glass jar.

In 3 hours the tablets completely disintegrated and the solution was stirred from time to time during the first 12 hours and less frequently on the 2nd day by the end of which all stirrings ceased and the solution allowed to stand for 24 hours. All the pill-binding material had settled at the bottom as a white precipitate leaving a perfectly clear supernatant fluid. This was siphoned into Erlenmeyer's flasks. This solution was boiled after adding about 15 c.c. of distilled water to about 700 c.c. of solution to compensate for the water lost by evaporation. The solution was boiled for exactly 3 minutes and then allowed to cool. It was ready for injection. Each 3 c.c. of this solution contain 0.1 gramme of quinacrine hydrochloride.

It is to be noted that the solution does not stand autoclaving or prolonged boiling. We tried autoclaving under 15 lb. pressure and a precipitate formed at the bottom of the ampoule. Prolonged boiling has the same effect. Both these processes made the solution unfit for parenteral use.

It was also found that certain brands of quinacrine or mepacrine tablets did not give as clear a solution as the Lilly brand which was used in most of the cases, otherwise the solution had to be filtered through a small sand filter made in a funnel, using cleaned and sterilized sand. This process was resorted to as filter paper was very costly and difficult to obtain.

Method followed

Quinacrine solution was always injected intramuscularly into the gluteal muscles. Only one injection of 9 c.c. or 12 c.c. was given to each case irrespective of the stage of the fever. There was much local soreness at the site of injection. Kneading for a few minutes after the injection reduced the after soreness to a minimum but it was not advocated except in case of females as it was found that in those cases where pain and tenderness at the site of injection had persisted for ten days to two weeks invariably there were no relapses.

The patient was given a dose of alkali containing 20 grains of sodium bromide and sometimes 10 grains of aspirin according to necessity. No quinacrine was advocated by mouth the same day. The patient was always given half to two and a half days' leave from mill work and was not at least allowed to go back to the factory on the day after he had received an injection. This precaution was taken as a few patients had felt giddy and in the terrific noise inside the factory had actually fallen down.

When the patient returned from leave (maximum 2½ days) he was given quinacrine by mouth to make up the total up to 1.5 grammes.

In all the above cases without exception there was no rise in temperature after the current spell of fever had subsided.

The patient was back to work usually on the 3rd day and at the latest on the 4th day.

TABLE II
Cases treated

	Quantity injected per case, c.c.	Number of injections per case	Number of cases treated	Number of relapses	Percentage relapse	Afebrile period in days
Group I ..	9	1	2,014	279	13.3	7 to 34
Group II ..	12	1	4,483	446	9.9	13 to 29
		TOTAL ..	6,497	725	Mean 11.6	

In a very small percentage of cases the fever persisted after the injection from 12 hours up to 3 days. In these cases only alkaline bromide mixture was continued until the fever subsided. Quinacrine tablets or solution was used orally only after the fever had subsided.

Untoward symptoms.—So much adverse opinion among the public against use of yellow tablets had been created that we first started using the tablets with some difficulty and had to camouflage the mepacrine in a mixture form. The injections of quinacrine had to be declared as a new kind of injection for malaria. Majority of patients showed no symptoms of intolerance to quinacrine.

In this series of 6,497 cases there were only 59 cases of minor symptoms such as feeling of heat in the head, giddiness, palpitation, slight epigastric pain and intense headache.

There were only 2 cases with major mental symptoms. These patients had to be hospitalized.

In both these cases the patient became violent and maniacal within 4 hours of the injection. They had to be controlled by 3 or 4 men and the clinical picture was very similar to that of acute alcohol poisoning. Alkaline glucose 25 to 50 c.c. intravenously every 3 hours and hyoscine 1/100 grain after every 6 hours (not more than 2 injections were needed) quietened down the patients to a great extent quickly. An alkaline bromide mixture containing 20 grains of sodij bromide per dose was continued by mouth every 4 hours. Both the patients became well within 60 to 72 hours.

Thus it will appear that the demerits attributed to quinacrine by certain sections of people seem to be an exaggeration.

Solution of quinacrine used by mouth was prepared by taking the unboiled solution prepared in the manner above described, and making up the 3 c.c. into 1 ounce by adding tap water and colouring the solution with methylene blue. This effectively camouflaged the yellow colour of the mepacrine and had a very pleasant hue, and the patients who objected to the tablets gladly took this mixture like the old quinine mixture thrice daily after food.

Summary and conclusions

1. Quinacrine hydrochloride in the treatment of malarial fevers has been used parenterally in

6,497 cases very effectively with a mean relapse rate of 11.6 per cent.

2. Parenteral use of the drug has reduced the labour absenteeism and consequent loss of wages by fully 50 per cent.

3. There were only two cases of major mental symptoms among 6,497 parenterally treated cases who completely recovered by the 4th day and the minor symptoms of intolerance were outweighed by the antimalarial efficiency of the drug. There was no fatality in the series of 6,497 cases.

4. Parenteral use of quinacrine is a very effective armament in our hands in a fight against malaria in an epidemic particularly among the labour forces.

INCIDENCE OF MALARIA IN CALCUTTA CITY

By S. SEN, M.B., D.T.M.

and

B. C. BASU, D.Sc.

(From the Calcutta School of Tropical Medicine)

It is rather difficult to say to what extent malaria is at present endemic in Calcutta city. Rogers (1906) reported 175 European malaria cases (*Plasmodium vivax* 79, *P. malariae* 3 and *P. falciparum* 93) who were admitted to the Presidency General Hospital during the period September, 1904 to December, 1905. Lukis (1907) recorded 119 malaria cases (*P. vivax* 41, *P. malariae* 2 and *P. falciparum* 76) who were admitted into the Calcutta Medical College Hospital during one year. Megaw (1907) noted 301 malaria cases (*P. vivax* 100, *P. malariae* 25 and *P. falciparum* 163; *P. vivax* and *P. malariae* 2; *P. vivax* and *P. falciparum* 10; and *P. malariae* and *P. falciparum* 1) in one year in the Outpatient Department of the Calcutta Medical College. He further noted that nine-tenths of these cases were domiciled in Bengal. Rogers (1919) gave the figures for the European hospital malaria cases observed in two years in Calcutta which were 200 (*P. vivax* 96, *P. malariae* 5 and *P. falciparum* 99). Knowles and Senior White (1930) reported 697 positive cases for malaria (*P. vivax* 232, *P. malariae* 73, and *P. falciparum* 392) as observed in four years, namely 1925 to 1928, in the Outpatient Department of the Calcutta School of Tropical Medicine.

Covell (1932) showed that the spleen indices among municipal school children, aged 6 to 10 years, varied from 0 to 3.8, with parasite indices from 0 to 15 in different wards of the city. The total number of positive cases recorded was 85 (*P. vivax* 17 and *P. falciparum* 68). Knowles and Basu (1934) reported 1,633 malaria cases who were admitted as in-patients at the Presidency General Hospital, the Indian Military Hospital and the Calcutta Medical College Hospital for the years 1928 to 1931 inclusive. An analysis of the malaria cases who attended the Outpatient Department of the Calcutta School of Tropical Medicine was conducted by the authors for the period between 1925 and 1935 (both the years inclusive). The total number of cases was 2,095, of whom 640 showed infection with *P. vivax*, 226 with *P. malariae*, 1,077 with *P. falciparum*, 124 with a mixed infection of *P. vivax* and *P. falciparum*, 13 with *P. vivax* and *P. malariae*, 9 with *P. malariae* and *P. falciparum*, 3 with *P. vivax*, *P. malariae*

and *P. falciparum* and lastly, 4 with malarial infection, the species of which could not be determined. The detailed figures are shown in table I.

Out of these cases the highest peak was seen in 1932 and lowest in 1935. The annual incidence of the cases, as observed, is represented in chart I.

A study of the seasonal incidence of these cases reveals that the highest peak was in November and the lowest in April. August, November, December and January are the months when comparatively more cases attended the Outpatient Department. The detailed figures are shown in table II and also represented in chart II.

As to the relative incidence of the three species of the above malaria cases (total figures for 11 years), *P. falciparum* was most prevalent, then came *P. vivax* and lastly *P. malariae*. Table III showing detailed figures will corroborate this statement.

TABLE I
Annual incidence of malaria cases

The relative percentage of the three species of the above cases, when taken on a monthly basis, shows that, except in April and June, *P. falciparum* has got a predominating character for the

Chart I showing annual incidence of 2,095 malaria cases (1925 to 1935).

TABLE III
Incidence of the three species

Species	Number of cases	Percentage
<i>P. falciparum</i> ..	1,077	55.5
<i>P. vivax</i> ..	639	32.9
<i>P. malariae</i> ..	226	11.6

Chart II showing the seasonal incidence of 2,095 malaria cases (1925 to 1935).

remaining ten months of the year. During April and June *P. vivax* shows predominating character which might be explained by the fact that this rise is due to the spring relapse of the species; for the remaining ten months of the year this species is less predominating than the former one. As to *P. malariae*, this species is at the lowest level throughout the year. The above statement is represented by table IV. Chart III shows the seasonal incidence of the three species of malaria separately.

Chart III showing the seasonal incidence of three species of malaria separately.

TABLE IV
Relative percentage of three species of malaria

Out of those cases, 778 were gametocyte-carriers. The peak of the gametocyte-carriers

was in 1932 which exactly coincides with the peak of the total cases (*vide* chart I) and falls in the curve also coincide with those in the curve of total cases. This statement is represented by table V and chart IV.

Chart IV showing annual incidence of 778 gametocyte-carriers (1925 to 1935).

TABLE V

Showing gametocyte-carriers

Years	B.T.	Q.	M.T.	Mixed infection	Total
1925	2	5	42	..	49

TOTAL ..	251	123	389	15	778

Monthly incidence of the gametocyte-carriers reveals that the highest number of crescent-carriers (*P. falciparum*) was found in December and the lowest in June. The highest number of gametocyte-carriers of *P. vivax* was in August and the lowest in October; as to *P. malariae*, the number of gametocyte-carriers was at a low level throughout the twelve months of the year.

Table VI will represent the detailed figures of the above statement.

TABLE VI

Showing detailed monthly figures of gametocyte-carriers (1925 to 1935)

TOTAL ..	251	123	389	15	778

As to treatment, those cases diagnosed as malaria but not willing to take admission into the hospital or not admitted into the hospital for want of accommodation, were given standard treatment from the Outpatient Department. Though there are some cases which are undoubtedly of local origin a large number of infections are acquired by persons who go out of Calcutta to malaria-infested places in the rural areas during the puja holidays.

This has already been pointed out by Covell (1932) and Knowles and Basu (1934). Besides this, Calcutta being a treatment centre of the province, people generally come from outside for treatment and most of them stay in Calcutta till their recovery and thus serve as a potential source of danger to the health of the city in the presence of notorious malaria-carrying mosquitoes and so many gametocyte-carriers. At the same time this analysis shows that there is a regular fall of the number of cases from 1932 to 1935 and if this fall continues it may become necessary to have the co-operation of other medical institutions of the city in having their malaria cases transferred into the Carmichael Hospital for Tropical Diseases or to open a malaria centre near Calcutta to obtain cases for conducting researches on malaria in the Calcutta School of Tropical Medicine. Incidentally each hospital of the city, which will treat malaria cases, should have mosquito-proof accommodation for keeping them just as fly-proof accommodation is provided for cholera cases.

Summary

The incidence of malaria eases (all three species together), diagnosed at the Outpatient Department of the Calcutta School of Tropical Medicine during the period of eleven years, namely, 1925 to 1935, was 2,095, of whom 778 carried gametocytes. The highest peak of malaria cases as well as gametocyte-carriers was in 1932. As to seasonal incidence from

February to July their numbers were at a low level and from August to January their numbers were comparatively increased having the highest peak in November. On a study of the relative percentage of the three species of malaria it was seen that *Plasmodium falciparum* was decidedly the predominating species, then came *P. vivax* and lastly *P. malaria* being in the lowest level; from April to June *P. vivax* showed a predominating character which might be due to the spring relapse of the species.

The writers' grateful thanks are due to Sir R. N. Chopra (then) Director and the late Professor B. M. Das Gupta for giving all sorts of facilities for this analysis.

PHENYL CELLOSOLVE IN THE TREATMENT OF PEDICULOSIS

By D. N. ROY, M.D., D.T.M.

and

S. M. GHOSH, M.B.

From the Department of Medical Entomology, School of Tropical Medicine, Calcutta

DAVIS and his co-workers (1944) experimented with phenyl cellosolve (monophenyl ether of ethylene glycol) using a mixture of phenyl cellosolve, ethanol and water in proportions of 1 : 2 : 2 with enough methyl salicylate to give it a slight pleasant odour. The material was used against head lice. The results, though not fully evaluated, were however thought to have been completely satisfactory.

Hansens (1945) later carried out tests on the heads of school children with mixtures containing 20, 10, and 5 per cent phenyl cellosolve respectively. When examined at intervals after treatment it was noticed that all lice and eggs were killed by all three concentrations. The composition of the weakest preparation was 5 per cent phenyl cellosolve, 37.5 per cent alcohol, 56.5 per cent water, 0.9 per cent methyl salicylate and 0.1 per cent 'Tergitol' penetrant 7. No toxic effects were noted with any of the preparations.

Messrs. Carbide and Carbon Chemicals Corporation, New York, the manufacturers of phenyl cellosolve, were kind enough to place an adequate quantity of this material at our disposal for experimentation on lice.

Laboratory studies on the penetrative properties of this mixture into the substance of

the nit, as can be deduced from the surface tension, were made by pouring a minute drop on a big surface of water. The rapidity and the extent of its spread were very suggestive of its ability to pass through the pores of the operculum and reach the embryo within the nit.

In order to determine the actual efficacy of phenyl cellosolve against eggs of lice, nits attached to hairs were just dipped in the mixture and were quickly taken out. These were examined from day to day. In all cases so treated the nits did not hatch.

The experiments conducted by us were carried out on hospital patients and for the purpose of evaluating the results only those who stayed for at least two weeks after treatment have been considered.

The mixture was applied to the hair of the scalp by means of a wad of cotton wool, sufficient quantity being used to wet the hair thoroughly. Care was taken to prevent the fluid from running into the eyes.

The tests were made on 22 patients of different ages varying from 4 years to 54 years, and except 2 patients, all were females and all had long hair. The infestation was generally heavy and in every case both adult lice and nits were present. All tests were made with preparations containing 5 per cent phenyl cellosolve and in 8 cases isopropanol instead of absolute alcohol was used. The composition of the mixture was as follows :

Phenyl cellosolve	..	5 c.c.
Absolute alcohol or isopropanol	37.5 c.c.	
Water	..	57.5 c.c.

It is worth noting that phenyl cellosolve does not mix with any mineral oil, nor with rectified or methylated spirit.

When necessary the patients were allowed to wash their hair two hours after the treatment was completed.

The results showed that phenyl cellosolve when used in 5 per cent strength is potent against both adult lice and nits. Regarding any untoward symptoms, only two patients complained of slight sensation of heat and tingling which were not marked and these passed off within 5 minutes. There were no remote effects.

The above preparation was also tested against *Phthirus pubis* on a patient who was heavily infested. Both adults and nits were found on beard, and on hairs on the axillæ and in the pubic and perineal regions. Only one application brought about the destruction of the louse population including the eggs.

In passing it may be mentioned that we have noticed for the first time the presence of *P. pubis* on beard and on axillary hairs in sufficient numbers.

Tests with the same material on heads complicated with secondary pyogenic infection and ulceration are in progress and the results will be communicated in due course.

One of us reported a short time ago on the successful treatment of pediculosis of the head with pyrethrum extract diluted with kerosene. This affects both adult lice and nits and only one application is necessary to effect a cure (Roy, 1946).

SPOROTRICHOSIS OF THE SKIN IN INDIA

(A NEW SPECIES DESCRIBED) *

By D. PANJA, M.B. (Cal.)
 N. C. DEY, B.Sc., M.B. (Cal.)

and

L. M. GHOSH, M.B. (Cal.), D.T.M. (L'pool)

School of Tropical Medicine, Calcutta

(Financed by the Indian Research Fund Association)

In a tropical country like India the incidence of sporotrichosis is expected to be common with other dermatomycosis, but excepting one case there is no other record on the subject. This scarcity of reports may be due to actual rarity of the disease or its non-recognition by physicians. The only case reported was by one of the authors (Ghosh, 1932). During the last 15 years 12 more cases have been recorded at the School of Tropical Medicine, Calcutta, but those were clinically diagnosed without any laboratory confirmation.

The incidence of sporotrichosis as recorded in other countries is more common amongst farmers, gardeners, florists, industrial workers, etc., and the case under report falls in the first group.

Case report.—An Indian female, 40 years old, a vegetable dealer by occupation. She had a small ulcer about $\frac{1}{2}$ inch in diameter on the lateral side of the right wrist and a small nodule $\frac{1}{4}$ inch in diameter about 4 inches proximal to the ulcer. The patient gave a history of a slight injury—a prick—at the site of the ulcer while handling vegetables. It healed up soon; but subsequently a small nodule developed at the site, red, hard and painful; this gradually softened and burst into an ulcer with sero-purulent discharge. Another nodule appeared very soon about 4 inches above the first one when she came for medical help. The second nodule was red, painful and softening at the time of examination.

Clinical findings.—Blood serum—Wassermann reaction and Kahn test were negative.

Blood count—Within normal limits.

Urine analysis—Normal.

Diagnosis.—The nodule was incised and the material from it was put up for culture in

Sabouraud's medium. On the 7th day a visible growth appeared on the surface of the medium. Microscopic examination showed the growth to be a sporotrichum.

Treatment.—The patient was put on potassium iodide grs. x three times daily and recovered soon.

Study of the fungus.—The primary culture was made on Sabouraud's proof medium. A visible growth appeared on the 7th day at room temperature (varying from 22° to 32°C.). At first it was cream coloured and raised with uneven and corrugated surface. As the age increased the colour changed to brown and then to dark brown and the growth became wrinkled and cerebriform at the centre but flush with the surface of the media at the periphery (see figures 1a and 1c, plate IX). In old cultures excrescences appeared on the surface of the growth (see figure 1b, plate IX). On potato the growth was appreciable on the 6th day, cream white in colour at first but gradually blackening. In a month's time the entire surface of the potato was covered with thick, coal-black cerebriform growth. In other common laboratory media the growth was like that on the Sabouraud's medium.

Microculture in hanging drop preparation.—Growth was profuse, the mycelial hyphae were septate and about 2 microns in diameter. The conidial spores were either round or oval, mounted on short stems (sterigma) and situated along the length of the mycelium and also grouped in fours or eights at the ends of the mycelial branches. The round spores were about 3.2 microns in diameter and the oval ones about 4 microns in length and 3 microns in breadth. Chlamydospores were very few (see figure 2, plate IX).

Biochemical reactions.—

Glucose gelatine—Growth was satisfactory, gelatine not liquefied (18° to 20°C.).

Serum (inspissated)—No proteolysis.

Litmus milk—No change.

Fermentation of sugars—Sugar fermentations were remarkably constant on repeated experiments. The original culture and cultures of the fungus recovered from experimental passage through laboratory animals gave the same reaction, viz, acid without any gas formation in dextrose, laevulose, maltose, galactose, mannose, dextrin, xylose and mannite (late fermenter). There was no reaction in lactose, sucrose, inulin, sorbite, inositol, arabinose, adonite and raffinose.

Pathogenicity to animals.—The fungus was pathogenic to all the laboratory animals, e.g. mice, rats, guinea-pigs and rabbits. Intra-peritoneal injections of an emulsion produced typical lesions on the testes, such as multiple abscesses developing into caseating ulcers with intensive destruction of the glandular tissue. The virulence of the fungus was intensified by passage through animals, as in the later experiments the animals had very severe infections

* Read in the Indian Science Congress, January 1947.

TABLE
A comparative table showing differences of various pathogenic species of *sporotrichum*.

Name of species	Character of growth	Optimum temperature of growth	Colour in different media	Mycelia and their size	Conidia	Shape and size of conidia	Glucose gelatine	Sugar reaction	Serum	Pathogenicity	Fungus in infected tissue
<i>S. tropicale</i> (the new species).	Cerebri-form, convoluted.	22°-32°C. No growth at 37°C.	Sabouraud—cream at first; brown to deep brown later. Potato—cream changing to black.	1.6-2µ in diameter.	Numerous, on sterigma; groups of 4 to 8. Terminal or lateral.	Round—3.2-4µ in diameter. Oval—3×4µ.	No liquefaction at 18°C.	Lactose —* Sucrose — Inulin — Mannite + (late) Glycerine + Dextrin +	No proteolysis.	Very pathogenic to mice and rats and also to guinea-pigs and rabbits. Do.	Round bodies in groups. Bacterial form present.
<i>S. beurnmanni</i>	Cerebri-form, convoluted.	22°-32°C. Slow growth at 37°C.	Sabouraud—white at first then dark brown. Potato—cream changing to black.	2µ in diameter.	Numerous, sterigma rare; terminal or lateral.	Pyriiform 1-2×0.5µ long. Round or oval 3-5×2-4µ.	Slight liquefaction.	Lactose — Sucrose + Inulin + Mannite — Glycerine + Dextrin —			
<i>S. schenckii</i>	Radiating furrows from the centre.	30°-38°C.	Sabouraud—white or light brown. Potato—yellow becoming brown.	Undulating. 2µ in diameter.	Few, on sterigma; lateral.	3-5µ in diameter. Oval or apiculate.	Slow liquefaction.	Lactose + Sucrose — Other sugars not known.	No proteolysis.	Very little.	Yeast like 3-5µ or bacterial form.
<i>S. jeanselmei</i>	Like <i>S. beurnmanni</i> or tomentose.	35°-37°C.	Sabouraud—creamwhite to old ivory. Potato—glucose-cream to coal-black 14th day.	1.5-2µ	Tufts of 4 to 5 spores, on sterigma; terminal or lateral.	Round 2.5-3.5µ. Pyriiform 4×2.4µ.	No liquefaction.				
<i>S. asteroides</i>	Like <i>S. beurnmanni</i> or <i>S. schenckii</i> .	30°C. Growth slow at lower temperature.	Sabouraud—first white later black. Potato—no pigment.		Lateral or terminal.	4-8µ	Slow liquefaction.			Rats and mice.	Spherical bodies 4-12µ with ray shaped radiating bacillary bodies, suggesting those of <i>Actinomyces</i> bodies. Yeast form present.
<i>S. carougeaui</i>	Like <i>S. beurnmanni</i> .	19°-22°C.	Sabouraud—cream. Potato—white or greyish.	2.5-5µ (mean 3µ).	On sterigma	Ellipsoid 2×4µ later spherical, 4-5µ in diameter. Pyriiform 7.6×2.5-3.5µ.	Liquefaction.				
<i>S. counclimani</i>		30°C.		1-1.2µ	Numerous on sterigma, solitary or in clusters. No lateral conidia.					Rabbits and guinea-pigs.	Branching filaments in lesion.

Spaces have been left blank where the details are not available. Sugar reaction: — + indicates acid formation; — no acid formation. * For other sugars vide text.

and died rapidly. From all the experiments the organism was recovered in pure cultures.

Identity.—Compare table.

Character of the growth.—Like that of *S. beurmanni*, but unlike *S. beurmanni*, the growth of this fungus ceases at 37°C.

Colour of the growth.—Like that of *S. beurmanni*.

Morphology.—Spore formation is different from any known pathogenic species in the size and character of the spores.

Pathogenicity.—Like *S. beurmanni*.

Biochemical reaction.—Different from *S. beurmanni* and *S. schenckii* in some respects but widely different from other pathogenic species.

From the above it seems that the fungus under study is not identical with any known pathogenic species.

Discussion.—There is still some difference of opinion as to whether *S. schenckii*, the American type, and *S. beurmanni*, the European type, are one and the same species. These two have been differentiated (a) on the difference of colour in the growth and (b) some difference in their biochemical reactions on sugars.

It is well known that the colour of the growth of a fungus varies enormously with the difference in the culture media, the temperature and the oxygen tension. Hence the colour variation in the growth cannot be regarded as a reliable factor in differentiating the species.

The biochemical reaction on sugars is a more reliable point for differentiation than the colour variation in the growth.

The species under study resembles the European type *S. beurmanni* in (1) character of the growth, (2) colour of the growth and (3) pathogenicity. But it differs from *S. beurmanni* in (1) optimum temperature of the growth, (2) spore formation and (3) biochemical reactions in sucrose, inulin, dextrin, glucose, gelatine, etc. (*vide* table).

Conclusion.—As the fungus cannot be identified with any of the known species it is proposed to be named *Sporotrichum* (Rhinoeladium) *tropicale* n.sp.

Summary

(a) A case of sporotrichosis of the skin in an Indian female vegetable dealer is described.

(b) Literature on this subject is very scarce in India; this is probably the second authentic case reported from this country.

(c) The species is pathogenic to common laboratory animals.

(d) Detailed mycology shows that the colour of the growth resembles the European type species *S. beurmanni* but it differs from *S. beurmanni* in its biochemical reactions, morphology and some other points.

(e) It differs from other known pathogenic species in many respects.

(f) It is proposed to name this new species *Sporotrichum* (Rhinoeladium) *tropicale* n.sp.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIEUTENANT-COLONEL, I.M.S.

(From the Laboratory of the Imperial Serologist and Chemical Examiner to the Government of India, School of Tropical Medicine, Calcutta)

THE KAHN TEST FOR SYPHILIS

A ONE-TUBE Micro-Kahn test, specially in conjunction with the Wassermann test, is as good as the full test. It is performed as follows:—

The apparatus.—(i) Small wooden racks about 12½ inches by about 1½ inches (at the bottom) by 1½ inches, to hold 18 miniature test tubes, the bottom shelf painted black and the rest white, and the top numbered for the tubes. Each rack is also numbered. (ii) Durham's fermentation tubes measuring about 5 cm. by 8 mm. with internal diameter of 6 mm. A fermentation tube not admitting a pipette should be rejected. (iii) Antigen-suspension vials* measuring 5½ by 1½ cm. as prescribed for the regular test. (iv) A 0.1 c.c. pipette graduated to the tip in 0.01 c.c. divisions for distributing antigen dilution. A Kahn pipette graduated to the tip or a Wright's pipette calibrated with mercury may be used. The pipette is worked with a teat. (v) Thin 1.0 c.c. pipettes graduated to the tip in 0.1 c.c. divisions for distributing serum and saline. (vi) Incubator registering 37°C. (vii) A magnifying glass. Items i to vii are shown in the photograph.

* The titration of the antigen is effected as follows:—

Pipette 1 c.c. of standard sensitized antigen into an antigen suspension vial. Pipette an amount of normal saline, indicated by the titre, into a similar vial. Pour the saline into the antigen and, as rapidly as possible (without waiting to drain the vial), pour the mixture back and forth six times. Allow the antigen suspension to stand ten minutes at room temperature before using. The suspension should not be used after 30 minutes' standing.

0.7 c.c. of the antigen (minimum recommended by Kahn) diluted with the necessary quantity of saline (as indicated by the titre) suffices for about 100 tests.

Determination of the titre itself is carried out as follows (see table):—

(A) Primary suspension of antigen.

Measure 0.7, 0.9, 1.0, 1.1, 1.2 c.c. respectively of physiological salt solution into 5 standard antigen suspension vials (5.5 cm. length, 1.5 cm. diameter).

Measure into each of 5 similar vials 1 c.c. of cholesterolized antigen.

Prepare 5 antigen suspensions by mixing the 1 c.c. quantities of antigen with the varying amounts of saline in series. Empty the saline into the antigen and as rapidly as possible (with waiting to drain the tube) pour the mixture back and forth 6 times. Permit the mixture to stand for 30 minutes.

(B) Secondary suspension from primary suspension to determine dispersibility of aggregates on further dilutions of saline.

Pipette 0.05, 0.025 and 0.0125 c.c. quantities of each of the five antigen suspensions, beginning with the suspension containing the largest amount of salt solution, in series, to the bottom of a set of five series of 3 standard tubes (employed in performing the regular Kahn test with serum, 7.5 cm. length, 1 cm. diameter), using a 0.2 c.c. or 0.25 c.c. pipette marked in 0.001 or 0.0125 c.c. amounts.

The procedure.—(1) Deposit 0.01 c.c. of the antigen dilution at the bottom of the tubes. Only the bottom division of the pipette is used and the antigen dilution shaken every time before drawing it into the pipette. (Antigen dilution taken to fill a pipette and then distributed division by division will not keep a constant density throughout.) (2) Also deliver 0.1 c.c. of an inactivated (not below 55°C. or above 56°C.) and clear (no particles) serum to be tested to each corresponding tube without delay. This is best done by an assistant who follows the deliverer of the antigen. (3) Put up (i) a known positive, (ii) a known negative and (iii) the antigen control, with saline, 0.1 c.c.

rack (reflected light). The reading is also aided by a magnifying glass.

Types of reactions.—The reactions are read on a plus sign basis.

(i) Four plus reactions—definitely visible particles suspended in a clear medium.

(ii) Three plus reactions—definitely visible but less clear-cut particles suspended in a clear medium.

(iii) Two plus reactions—particles suspended in a somewhat turbid medium.

(iv) One plus reactions—very fine particles suspended in a somewhat turbid medium.

(v) Doubtful, \pm , reactions—mere granularity when compared with controls.

TABLE FOR TITRATION OF ANTIGEN

A. Primary suspensions

Tube number	..	I	II	III	IV	V
Antigen in c.c.	..	1.0	1.0	1.0	1.0	1.0
Saline in c.c.	..	0.7	0.9	1.0	1.1	1.2
Appearance of mixture		Heavy suspension of aggregates.	Heavy suspension of aggregates.	Heavy suspension of aggregates.	Heavy suspension of aggregates.	Heavy suspension of aggregates.
		Kept for 30 minutes				

B. Secondary suspension from primary suspensions to determine dispersibility

	From I			From II			From III			From IV			From V				
Tube number	..	1	2	3	1	2	3	1	2	3	1	2	3	1	2	3	
Suspension in c.c.	..	0.05	0.025	0.0125	0.05	0.025	0.0125	0.05	0.025	0.0125	0.05	0.025	0.0125	0.05	0.025	0.0125	
Saline in c.c.	..	0.15	0.15	0.15	0.15	0.15	0.15	0.15	0.15	0.15	0.15	0.15	0.15	0.15	0.15	0.15	
		Shake for 3 minutes			Shake for 3 minutes			Shake for 3 minutes			Shake for 3 minutes			Shake for 3 minutes			
More saline in c.c.	..	1.0	0.5	0.5	1.0	0.5	0.5	1.0	0.5	0.5	1.0	0.5	0.5	1.0	0.5	0.5	
Appearance of mixture		Cloudy (visible aggregates present).			Cloudy (no visible aggregates present).			Cloudy	Opalescent (transmits images of windows across the street).		Opalescent.		These tubes give the titre, i.e. the dilution of the antigen should be as in IV (1 c.c. of the antigen + 1.1 c.c. of saline).			Opalescent.	

only, instead of serum. (4) Shake the racks vigorously for 2 minutes and place into the incubator at 37°C. (5) Remove the racks from the incubator after 15 minutes and add 0.2 c.c. saline into each tube.

The ensemble :—

Antigen dilution	0.01 c.c.
Serum	0.1 c.c.
	Shaken for 2 minutes.		
	Incubated for 15 minutes.		
Saline	0.2 c.c.

Reading of results.—Results are read by holding the rack in front of a window (refracted light) aided by holding the index finger between the light and the tube, by the lower edge of the

With a 1 c.c. pipette, add 0.15 c.c. salt solution to each of the 15 tubes.

Shake the rack of tubes vigorously for 3 minutes by hand.

Add 1 c.c. salt solution to the tubes containing the 0.05 c.c. amounts of antigen suspension, and 0.5 c.c. to the remaining tubes. Observe whether fluids are opalescent or contain aggregates.

The smallest amount of saline, which when added to 1 c.c. of antigen, produces aggregates capable of complete dispersion upon the addition of further salt solution, yielding an opalescent fluid which is not cloudy, gives the titre of the antigen.

The titre is constant and need only be checked once a month or so.

(vi) Negative reactions—not different from the antigen control except for the colour and a slight influence of the viscosity of the serum on the movement of the opalescent fluid, like the known negative control.

Interpretation of reactions.—Four plus and three plus reactions are interpreted as positive; two plus and one plus as weakly positive; and doubtful and negative reactions are classed together and regarded as negative.

(To be continued)

INTUSSUSCEPTION FOLLOWING INFOLDING OF BOWEL

By N. S. MACPHERSON, F.R.C.S.

Associated Professor of Surgery

and

E. W. GAULT, M.D., M.S. (Melb.), F.R.A.C.S.

Professor of Pathology

Missionary Medical College and Hospital, Vellore

INTUSSUSCEPTION has been reported following the inversion of the appendical stump by the usual method practised in the operation of appendicectomy: the risk of its occurrence is sufficient as a reason for abandoning this

method of covering over the appendix stump. In 1943 Fraser collected four cases from the literature occurring at intervals varying between twelve days and four and half years after appendicectomy. It was the occurrence of cases such as these that led to the advocacy by many surgeons of covering the stump of the appendix with a tag of nearby fat instead of inverting it into the caecum or even of leaving it uncovered after cauterization of the exposed mucous membrane. That this complication 'must' be extremely rare is evident from the fact that so few cases have been reported out of the many thousands of operations for appendicitis performed by the 'orthodox' technique during the past fifty years.

The following case was one of intussusception originating in the inverted end of a loop of small intestine and could be placed in the same category as the above type of case :

The patient, a Hindu girl, aged 15, was admitted to the hospital on 14th September, 1945. For some fifteen months she had suffered at intervals from pains of a colicky nature beginning in the mid-abdomen and spreading to the left hypochondrium; these were associated with nausea and sometimes vomiting and were unrelated to the taking of food. One month before these attacks commenced she suffered from cholera. The duration of an attack would be 24 hours or even longer with intervals of freedom from pain lasting several weeks. For twenty days previous to admission she had been suffering from more or less continuous pain of this character.

On examination the patient appeared to be in fair general condition though clearly suffering from pain. There was slight fullness of the abdomen which moved normally on respiration. There was a visible swelling in the left upper quadrant which varied in size from time to time. There was some visible peristalsis in the upper abdomen. It was noticed that when the swelling became prominent the patient complained of colicky pain. On palpation an irregular mass could be felt above and to the left half of the transverse colon and its outline suggested a connection with this structure. Its dimensions were about six cms. from side to side by four cms. from above downwards. It could be moved slightly in all directions though it did not move with respiration. On percussion it was dull. There was no free fluid in the abdominal cavity. On auscultation very well-marked bowel sounds were heard over the upper abdomen. On rectal examination nothing abnormal was observed nor were there signs of disease in the rest of the body apart from a low haemoglobin 60 per cent (Sahli) and a high white count 21,000 cells per c.mm.

Abdominal exploration was carried out on 25th September, 1945. The mass was found to be retroperitoneal, hard and rather irregular with a loop of jejunum stretched out over it. The bowel was not invaded by the mass but

was clearly being kinked by pressure and so obstructed. The bowel and the mass were closely adherent to one another. There were some enlarged glands in the lower part of the mesentery one of which was removed for microscopical examination. The condition was thought to be tuberculous adenitis. Removal of the mass, however, was considered unpracticable and unnecessary (figure 1).

To relieve the obstructive symptoms healthy loops of bowel above and below the lesion were found and an end to side anastomosis performed (figure 2). For the anastomosis cotton sutures were used throughout and the blind end of the upper loop was serially closed by the ordinary method of two rows of continuous sero-muscular cotton sutures.

Fig. 1.—A diagrammatic representation of the small intestine showing the region obstructed.

Fig. 2.—Anastomosis of the jejunum proximal to the obstruction into the jejunum distal to the obstruction leaving a blind loop of bowel.

Convalescence was uneventful and the patient was discharged four weeks after operation.

The report on the gland was as follows : The normal structure of the gland is almost completely obliterated by an increase of small round cells resembling lymphocytes. A few proliferating germinal centres are visible here and there but the sinusoids cannot be made out. There is no caseation; no foci of epithelioid cells are seen, so that the condition does not appear to

be tuberculous. The cell picture is too uniform for Hodgkin's. On the whole the section suggests a non-specific chronic inflammatory reaction rather than neoplasia.

The patient was re-admitted on 18th January, 1946, with abdominal pain of 15 days' duration. The pain was severe, colicky in nature, and came on in frequent attacks every day. She said that she felt a lump moving about in the abdomen and described the pain as beginning in the left upper abdomen and moving to the right parts.

The patient's general condition was very poor. She was emaciated and dehydrated and was clearly suffering much pain. The abdomen showed general rigidity and tenderness and there was a mass 5×4 cms. in the region of the abdominal scar (*R. paramedium*). An examination by a barium meal was made at once. This showed delay in the passage of the barium meal through a dilated loop of jejunum which was situated about one foot from the beginning of the jejunum. There was very active peristalsis over this dilated loop. After a short delay the meal passed on. No displacement by a mass was found at this examination. Impression from this examination was partial obstruction in a dilated upper jejunal loop.

As there was no evidence of complete obstruction and as the patient's condition was far from suitable for operation the abdomen was not re-opened but an attempt made to relieve her symptoms and restore her nutrition by non-operative means. Her condition, however, deteriorated and she died twelve days after admission.

The autopsy was performed ten hours after death. The subject was a wasted and poorly developed girl. There was marked generalized dermatitis from scabies.

On opening the peritoneal cavity some sero-purulent fluid was encountered. The duodenum was distended as were also the first 12 cms. of the jejunum at the end of which the anastomosis had been performed. There was an adequate stoma and a well-healed anastomosis which had an adequate opening between the loops of bowel. The blind loop of bowel left at operation was found to extend to the left from this anastomotic site as a sausage-shaped swelling. The end of this loop showed an invagination of the bowel and mesentery resembling an intussusception (figure 3). When this loop was opened it was found to contain intussuscepted bowel and mesentery. The apex of the intussusception had reached the anastomotic site and was projecting into the bowel just beyond producing obstruction. When the apex was incised the cotton suture used for the purse string to infold the bowel at operation was discovered. Thus the apex of the intussusception was the place at which the closed end of bowel had been invaginated. This must have produced a small projection which proved to be the commencement of the intussusception (figure 4).

The base of the intussusception was beginning to become gangrenous and there was one area of ulceration on the peritoneal surface. The omentum was adherent to this region and was inflamed and gangrenous. There was a long

Fig. 3.—The condition as found at post mortem. A. The intussuscepted bowel from outside. B. Anastomotic site.

Fig. 4

Fig. 4.—The appearance when the blind loop of bowel was opened to show gangrenous intussuscepted bowel and mesentery. B. The anastomotic site at which point the intussuscepted bowel was obstructing the lumen.

adhesion formed from omentum stretching from this site down to the right iliac fossa. There was some dilatation of the upper part of the small intestine but the peritoneum was shiny and there was no evidence of generalized peritonitis. In spite of a very careful search no evidence was found of the mass found at the

first operation. The bowel was not freely movable but was bound down to the posterior abdominal wall.

The spleen was adherent to the stomach over most of its gastric surface and there was a small amount of yellowish pus in this region.

The right lung was firmly adherent to the chest wall by old white adhesions between visceral and parietal pleuræ which were difficult to separate. In this separation some of the superficial part of the lung remained adherent to the chest wall. On the left side the adhesions were not so marked and were mainly seen at the base of the lung. On section the lungs were seen to be markedly anthracotic with enlarged anthracotic glands at the bifurcation of the trachea and on either side of the trachea itself. Both lungs were red and crepitant with no areas of consolidation.

Examination of the intussusception microscopically failed to reveal any areas of tubercular infection.

Comment.—The extensive pulmonary adhesions in a girl of 15 suggest the possibility of a tuberculous pleurisy. Anthracosis is commonly seen in India due to the very smoky kitchens in most homes. The mass found at operation could not be identified macroscopically or microscopically. Explanations that can be offered are that the rest resulting from short circuiting allowed resolution to take place in a tuberculous mesenteric gland or that complete degeneration had resulted from necrosis accompanying the intussusception; that the attack of cholera preceding the development of the signs of obstruction may have left a residual glandular mass is a further conjecture.

In connection with the subject of intussusception from invaginated bowel the following case is of interest as suggesting intussusception occurring several years following appendicectomy although absolute proof is lacking. For these notes we are indebted to Dr. H. M. Lazarus (Lieut.-Colonel, I.M.S.) who performed the second operation.

The patient was an Anglo-Indian woman, aged 49, who had had her appendix removed in 1926. Ten years later she was admitted to hospital complaining of epigastric pain, vomiting and the passage of blood and mucus in the stools for eight days. Her temperature varied between 99° and 101°. Repeated examination of the stools showed many red blood cells and a number of pus cells but no amœbæ or cysts. Abdominal examination showed a flabby abdomen with visible peristalsis extending across the abdomen and down to the sigmoid region. There was a sausage-shaped swelling extending from right to left along the line of the ascending transverse and descending colons as far as the sigmoid region palpable during spasms. Rectal examination showed a bulging in the pouch of Douglas.

At operation there was found an intussusception, the apex of which reached to the rectum.

This was easily reduced by pushing the apex backwards. The colour and blood supply of the bowel were normal. The intussusception had begun in the cæcum where there was some thickening of one of the tæniæ.

These two cases serve to indicate the definite possibility of invagination of the appendix stump or a blind loop of bowel being the starting point for an intussusception.

We are indebted to Dr. Ida B. Scudder for the x-ray report, to Dr. Agatha Crawford for the report on the gland, to Dr. Hilda Lazarus for her case notes and to Mr. Guiry for his drawings.

A CASE OF INIENCEPHALIC MONSTER

By P. S. DASTUR, M.S., B.M.S.

Professor of Anatomy, Grant Medical College, Bombay

A FULL-TERM female foetus (figure 1, plate VIII), the vertical length of trunk and head 15.2 cm.; anal, vaginal and urethric openings present on the external surface; no groove of neck seen from front or from behind, the skin passing straight down from the chin to the thorax, and from the back of the head to the back of the trunk. On the posterior aspect the hair of the head extended down to a point 5.5 cm. above the rump. Ears well developed, and situated in their normal position. No visible spina bifida on the surface. Large omphalocele 6 cm. × 5 cm. at the skin margin. The umbilical cord attached to the left side of the sac of the omphalocele. Both the feet showed talipes. The mouth pointed almost directly upwards, and the bregma pointed backwards and upwards.

A sagittal section was made (figure 2, plate VIII). It passed to the left of the middle line. The fusion of the occipital region to the back extended to the upper lumbar region. The foramen magnum was larger than usual and measured 2.6 cm. anteroposteriorly. The basi occiput was running vertically down. The cervical and the thoracic regions of the spine were making an acute curve with the concavity posteriorly. The sacral and the lumbar regions of the spine were closed, and pedicles and lamina had developed in these regions, but the spine of the cervical and the thoracic regions was open from behind and the laminae had not developed in these regions. There were fewer segments in the cervico-thoracic part of the spine than in a normal individual.

Though the foramen magnum and the cavity of the subarachnoid space in the cervical region were larger than normal, no part of the brain was situated below the foramen magnum. In the cervical part of the spinal cord the central

Fig. 1.

Fig. 2.

canal was open from behind and the cord itself was transversely broadened so that the open spinal canal resembled the fourth ventricle. The open canal was actually directly continuous with the cavity of the fourth ventricle above. The open upper part of the cord was closely following the curve of the cervico-thoracic curve of the canal. The lateral margins of the open part of the spinal cord were formed by thick vertical bands which were continuous with the posterior columns of the cord lower down. In the lower part of the open portion there was a transversely elongated, slightly pedunculated mass about 9 mm. in transverse diameter. Immediately in front of the bands mentioned above as forming the lateral margins of the open part of the spinal cord was a groove from which the nerve roots were emerging. That this open part was not the medulla oblongata itself was shown by the facts that normal medulla oblongata with pyramids and olive was present at the level of the cerebellum above the level of the foramen magnum, and the nerve roots that emerged from this part were emerging out between the cervical and thoracic vertebræ, thus showing definitely that this part was really the cord and not the medulla oblongata. The cavity of this open portion of the cord was continuous with the cavity of the fourth ventricle above and with the central canal of the cord below. In the mid-sagittal plane on the posterior aspect of the body of the vertebræ, opposite the transverse mass in the open part of the cord, was a small spine about 1 or 1.5 mm. projecting backwards towards the spinal cord. The lumbosacral region was normal and the spinal canal was closed.

The palatine processes corresponding to the premaxillary part had fused together in the middle line and with the nasal septum, but behind that portion there was cleft palate affecting the bony as well as the soft palate. The palatine processes had developed, but they had not fused in the middle line in the posterior part, leaving the cavity of the mouth in free communication with the nasal cavities. The nasal septum was well developed with its free inferior border opposite the cleft in the palate.

Both the kidneys were situated at a higher level and were projecting in the thoracic cavity through defects in the corresponding sides of the diaphragm. The crura of the diaphragm on each side of the aortic opening had developed and the defects above mentioned were on right and the left side of the corresponding crus. The whole of the liver and the spleen were in the sac of the omphalocele.

Iniencephaly was first described and named by Isidore G. Saint Hilaire who described the abnormality as very rare. The three chief characteristics of iniencephaly are retroflexion or backward bending of the spine, the spina bifida and large foramen magnum due to imperfect formation of the occiput in the

neighbourhood of the foramen magnum. There may be other associated abnormalities.

My thanks are due to Dr. K. M. Masani, M.D., F.R.C.S., chief medical officer, Wadia Maternity Hospital, Bombay, for lending me the specimen of dissection.

HERPES ZOSTER : TWO CASE STUDIES

By NOOR HUSAIN, M.B., B.S., D.P.H. (Edin.)

Chemical Examiner, H. H.'s Government, Jammu and Kashmir, Jammu (Tawi)

Case no. 1.—J. A., a young man, aged 19 years, otherwise in perfect health, experienced pain in the neck and left shoulder on or about the 9th September, 1946. He attributed it to a chill and some physician prescribed two aspirin tablets to be taken during the day. For 3 days in spite of the aspirins the pain did not subside. On the 4th day of the illness on careful examination no cause could be found for the pain, but on the 5th day on the left side of the neck just below the left ear two typically herpetic eruptions were noticed. The herpes soon spread to the neck below the ear and also on the face in front of left ear and a few vesicles appeared in the supra-clavicular region. On the appearance of the rash the intensity of pain was considerably relieved. Three days after the appearance of the rash the patient developed left facial paralysis (Bell). The eruptions also extended to the left occipital region.

The facial paralysis persisted. At the time of writing (20th January, 1947), i.e. after a lapse of 4½ months, it has just disappeared except that the left angle of the mouth is slightly drawn upwards and to the left when the patient smiles. The left eye could not be closed completely for about 2 to 3 months after the onset of paralysis.

Treatment.—Pituitrin 1 c.c. (intramuscularly) daily with local application of zinc-starch and boracic powder were resorted to. Only 6 c.c. of pituitrin were administered. The patient also received Berin injections 1 c.c. subcutaneously for about 10 days. Beyond that no other treatment was adopted. The general health of the patient was not much affected.

Case no. 2.—N. D., a robust and healthy male, aged 60 years, suddenly developed acute conjunctivitis in the right eye during the middle of November 1946. This seemed rather unusual in a person of a very clean habits with no case of acute conjunctivitis around. The left eye was totally unaffected. After three or four days of treatment with frequent saline *cum* boracic washes, and 10 per cent argyrol lotion locally, no improvement was noticeable. On the 5th day a rash appeared on the right forehead and it was typically herpetic in character. Herpes zoster of supra-orbital branch of the trigeminal nerve was diagnosed. The cornea was at once examined, and by use of fluorescein, a marginal ulceration was noticed at 6 o'clock. Immediately treatment with sulphathiazole by mouth (2 to

3 grammes daily) and homatropine ointment in the eye (after due regard for the tension) was adopted. Pituitrin 1 c.c. daily was given intramuscularly for 3 or 4 days. Sulphathiazole treatment was stopped after about 6 days as progress of the ulceration was checked. The rash started drying up after a week.

The inflammation of the eye cleared up after about 2 weeks, but the vision did not return to normal till after 20 to 25 days.

Discussion

1. Two unusual cases of herpes zoster have been described. Both are unusual in view of development of facial paralysis in one and involvement of cornea in the other.

2. In the case of supra-orbital herpes, a case of chicken pox had occurred in the family some 3 weeks prior to the onset of disease in this case. The relationship of the causative virus of chicken pox and herpes zoster is admitted in many quarters and this case seems to provide a further proof of the close association of the two.

3. Pituitrin therapy does not seem to be of much benefit, and since no immediate results were obtainable, the treatment with this biological product was cut short after certain number of injections.

4. Collodion flexile was not tried as a protective for the eruptions as in many cases it has been observed to cause great inconvenience to the patient.

5. Ordinary bland dusting powder seemed good enough for the eruptions.

A CASE OF DERMATOMYOSITIS

By L. M. GHOSH

and

B. K. SEN

School of Tropical Medicine, Calcutta

D. G., A TEN-YEAR-OLD Bengali girl, was admitted on 29th May, 1946, with the history of intermittent low pyrexia every evening, progressive weakness and a number of gradually extending skin lesions (see figure, plate X).

History.—About a year ago, she was suddenly attacked with fever followed by the appearance of a small erythematous patch on the left thigh. In course of time similar other lesions developed on other parts of the body one after the other. Later, the skin over some of the affected areas became adherent to the underlying subcutaneous tissue. In the sixth month of her illness she had a course of sulphanilamide with no effect.

Family history.—Nothing particular.

Physical examination on admission.—Patient appeared poorly nourished. Spleen—soft, enlarged almost down to the level of the umbilicus. Other organs—normal.

Cutaneous lesions.—Raised erythematous annular ridges enclosing slightly depigmented and atrophied areas. The lesions were not itchy but painful in certain places. The skin over some of the affected areas, specially the left elbow, was adherent to the underlying subcutaneous tissue.

Sites of the lesions.—Primary site—left thigh, oval with 4 inches longest diameter. Other sites—forehead, a semi-lunar area 3 inches in diameter; chest, round 7 inches in diameter; back, rectangular—6 inches \times 5 inches; arms, from near the shoulder joints to the elbows, the outer surfaces affected more than the inner.

Laboratory findings :—

Urine analysis—faint trace of albumen present, otherwise normal. *Urine culture*—sterile. *Urine creatinine*—1.3 gm. (in 24 hours). *Stool*—normal.

Blood count :—

Erythrocytes	.. 2,960,000 per c.mm.

10th August		
Blood creatinine	..	0.0036 gm. per cent
Urine creatinine	..	0.05 gm. per cent

Creatinuria is said to be one of the features of this condition but in this case there was no marked increase in the creatinine excretion nor any appreciable increase in the creatinine content of the blood.

Histopathology (Major K. Banerjee)—

Epidermis.—Moderate thickening of the horny layer which is partially detached here and there. Surface shows formation of crusts composed of dried up fibrin, R.B.C. in fairly large numbers and leucocytes. Stratum lucidum indistinct. Rete mucosum slightly hyperplastic. Basal cells contain fairly dense charge of melanin pigment which shows normal drift towards surface.

Corium.—Both pars papillaris and pars reticularis show fairly well-marked oedema and increase of fibrous tissue at the expense of normal soft collagen bundles. The papillary and sub-papillary plexuses are dilated, their endothelial cell wall shows appreciable swelling. Only scanty perivascular lymphocytic infiltration is noticed. Sebaceous glands and hair follicles are destroyed, coil glands are more or less intact, although a few show pressure distortion and commencing atrophy.

Subcutaneous tissue.—The interstitial tissue of the panniculus adiposus is densely infiltrated with small lymphocytes, plasma cells and histiocytes—all the blood vessels and capillaries are markedly dilated, the adventitia of the larger vessels show lymphocytic infiltration. The fat cells appear much larger than normal—their nuclei retain normal morphology. Groups of histiocytes are permeating along lymphatic spaces; there are no fibroblasts along these tracts of permeation indicating a condition of histophagy without formative fibrosis. The spread of cellular infiltration seems to be limited superficially by a thick band of fibro-collagenous tissue originating from the pars reticularis—a few multi-nucleated connective tissue cells are found lying free in the matrix substance. Irregular foci of fat necrosis are also to be seen. Deep fascia is somewhat oedematous—blood vessels are dilated, some of the veins contain thrombi while a few small clusters of histiocytes in the lumen. Scanty lymphocytic infiltration of the adventitia is evident in this region as well.

Changes in muscles.—All the muscles show advanced stage of degeneration of the entire bundles—the fibrils have lost their striations and nuclei as well in most instances—there is complete resorption; interstitial oedema of considerable degree and focal hæmorrhage without any evidence of infiltration with lymphocytes or histiocytes. Sarcolemma is very indistinct—the sarcoplasm is inclined to be basophilic. In some areas a diffuse patch of hæmorrhage represents the remnant of a muscle bundle.

Oblique tangential section of some of the less affected bundles shows thickening of the sarcolemma, well-marked interstitial oedema and duplication of nuclei.

Histo diagnosis.—Dermatomyositis (polymyositis).

Abnormal feature.—Dense cellular infiltration of the subcutaneous tissue.

Course in the hospital.—The patient was getting a daily rise of temperature in the evening, the maximum being 101°F. She was put on mixed diet consisting mainly of eggs, butter, bread, vegetables, milk, fish, orange and rice, and adexolin 10 drops twice daily. After about two weeks there was a little remission in the fever, the highest being 99°F. and the patient gained in weight but the skin lesions and the spleen underwent no change. Ten days after, the temperature started going up again and the patient was put on 5 grains of quinine sulph twice daily for four days, but with no effect. This was followed by penicillin injections intramuscularly 10,000 units every four hours up to 500,000 units without any effect. Walking short distances used to make her feel better, but there was no change in the temperature or the skin condition. She was then given intramuscular injections of milk every fourth day, beginning from 1 c.cm. and increasing every time by 1 c.cm. up to eight such injections. There was slight improvement in the temperature, skin lesions and the spleen. At this stage the patient went away from the hospital and since then there is no report about her.

The case is diagnosed as one of Dermatomyositis on the basis of histological findings although the clinical features do not conform to the classical description in standard works.

Therapeutic Notes

NOTES ON SOME REMEDIES

VIII. AMOEBCIDES

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
T.D.D. (Wales), F.S.M.F.

Professor of Tropical Medicine, School of Tropical
Medicine, Calcutta.

IPECACUANHA root was long used in Brazil as a remedy for dysentery and first brought to Europe nearly three centuries ago by Piso who had discovered its value during his tour of

exploration in that country. It was sold to the French Government as a secret remedy and after the successful treatment of Louis XIV its use became more general. It rose in popularity in the nineteenth century. At first small doses were used, later one dram doses were introduced. Leonard Rogers was the first to try injection of emetine, one of its alkaloids, and the results were spectacular. Although it has its limitations, emetine is still the basis of treatment of amœbic dysentery and its dangerous complications, hepatitis and hepatic abscess, but since then many other drugs and combination of drugs have been introduced, some containing emetine and others of a totally different nature, and these are used chiefly as supplementary to emetine. These drugs may be divided into five groups, the best known being as follows :—

- I. *Compounds of emetine*—
Emetine hydrochloride
 " bismuth iodide
 " periodide
Auremetine
- II. *Organic arsenicals*—
Carbarsone
Stovarsol (acetarsol)
- III. *Oxyquinoline derivatives*—
Chiniofon
Vioform
Diodoquin
- IV. *Chemotherapeutic agents*—
Penicillin
Sulphonamides
- V. *Miscellaneous*—
Kurchi
Bismuth salts

A brief description of the uses of these drugs is given below :—

I. *Emetine and its compounds*

1. *Emetine hydrochloride*.—In the human body emetine is rapidly absorbed when given by injection and acts on the amœbæ lying in the tissues of the intestine and of organs such as the liver, but although it is partly excreted by the gastro-intestinal tract, the amount is not sufficient to have any appreciable action on the amœbæ and the cysts lying in the lumen of the bowel. Excretion also takes place through kidneys, but this occurs irregularly and only in fractional amounts. Actually it accumulates in the body and may take several weeks to pass out of the body after a course of treatment is completed.

The dose of emetine hydrochloride is $\frac{1}{2}$ to 1 grain. The total dosage is calculated at 1 grain per stone body weight but in an average Indian patient it should not exceed 9 or 10 grains in one course. It is an advantage to give it in two parts with an interval in between, particularly in weak patients in order to diminish the toxic effects of cumulation. Thus to a patient

weighing 9 stones, a total dosage of 9 grains is given, of which 6 grains may be given in the first six days, and the remainder after three days in 1 or $\frac{1}{2}$ grain doses. There is no therapeutic advantage by giving heroic or protracted dosage which tends to poison the patient without any corresponding effect on the disease itself.

It is a common practice to give emetine injections subcutaneously but this may cause irritation and painful indurations persisting for long periods and even cellulitis. These disagreeable sequelæ may be obviated by intramuscular or deep subcutaneous injections. It should not be injected intravenously. As it is liable to cause toxic effects the patient should be at rest when undergoing treatment; a second course of emetine, if at all necessary, should not be given until after the lapse of a few weeks.

2. *Emetine bismuth iodide (E.B.I.)*.—This compound contains approximately one grain of emetine in every three grains and is given by mouth and is specially indicated in chronic cases. It is an almost insoluble powder from which the emetine is set free by contact with the intestinal juices, and it is therefore important that such contact should in no way be prevented by giving it in hard or compressed tablets, or made up with insoluble substances, such as vaseline, stearin or keratin. It is best given in powder form in gelatine capsules (slipules), but as these capsules tend to harden with time and become insoluble they should be pricked with pin before being administered. The dose is one grain on the first night and subsequently 2 grains, and is given at night, say about 10 p.m., four hours after a light meal. For women and delicate individuals the dose should be gradually increased. The patient should be in bed and resting quietly. There is a tendency to vomiting though a certain amount of tolerance to the drug develops later. This vomiting is to be expected and only shows that the drug is being absorbed. The patient should endeavour to sleep and the saliva should be wiped from the mouth or expectorated and not swallowed. If nausea and vomiting are troublesome, it is necessary to give 15 minims of tincture of opium or phenobarbitone 1 grain half an hour before each dose. The drug also causes some diarrhœa about midway or a little later in the course which lasts ten days, this is beneficial as thereby it comes in better contact with the amœbic cysts which live on the mucous membrane of the bowel and which are not affected by hypodermic emetine. Towards the end of the course depression and general weakness are noticed, there is some loss in weight and the blood pressure tends to fall. But the treatment should not be stopped or shortened unless severe prostration or cardiac depression supervenes. When the course is completed, the patient quickly recovers, but he should be gradually permitted to resume work.

E.B.I. is a very effective drug especially if combined with chiniofon enemas, but it must not be given in a form in which it is not absorbed. Its drawbacks are the nausea and vomiting which it causes.

3. *Emetine periodide*.—Its action is similar to E.B.I. but it is less toxic though not so effective. It is given in 3-grain capsules combined with capsules of dried ox-bile 5 grains which facilitate liberation of emetine. This drug is to be preferred for those who cannot tolerate E.B.I.

4. *Auremetine*.—It is a combination of emetine with the aniline dye, auramine. It causes some nausea but hardly any vomiting. The dose, 1 grain in gelatine capsule, is given four times daily on alternate days, usually combined, on other days, with stovarsol by mouth and chiniofon enemas, the whole course of treatment lasting 21 days.

II. Organic arsenicals

These act against the amœbæ whether they are in the tissues of the intestine or in its contents, but are mainly used to supplement the action of emetine. They should not be administered to patients in whom liver, kidney or retinal damage is suspected. *4 Bae -102.*

1. *Carbarsone*.—Next to emetine, it has perhaps the strongest action against *E. histolytica*. Mateer *et al.* (1941) state that carbarsone is the 'most effective amœbicidal drug now known.' From a study of the effects of various drugs (except yatren enemas and other iodine preparations) used singly in a large series of chronic amœbiasis Chaudhuri and Rai Chaudhuri (1946) found that carbarsone had the best action. Better results are obtained when combined with chiniofon enema. A dose of 0.25 gm. (4 gr.) in capsule is given twice daily for 10 days after food. As it is relatively non-toxic it can be repeated after ten days' rest.

2. *Stovarsol (acetarsol)*.—It has been widely used in amœbic dysentery, but its action by itself is weak. Its special indication is in the aftercare of amœbiasis. The usual course is one tablet of 4 grains each night and morning for 10 days. It is liable to produce toxic symptoms and has now been largely replaced by carbarsone.

Both stovarsol and carbarsone can be administered per rectum in the form of retention enemas of 2 gm. in 200 c.c. of warm 2 per cent sodium bicarbonate solution after a preliminary cleansing enema. Sodium amytal, 3 grains, is previously given by mouth to ensure sleep and facilitate retention of the enema. The drugs should not be given at the same time by mouth and rectum.

III. Oxyquinoline derivatives

These are combinations of oxyquinoline sulphonic acid and varying proportions of iodine.

They are efficient amœbicides, but being incompletely absorbed from the intestinal tract, have not much action on the amœbæ in the tissues of the intestine.

1. *Chiniofon* (also known as *yatren*, *quinoxyl*, *anayodin* and *quinosulphan*).—This is the oldest of the three drugs of the group and contains 27 per cent of iodine. It is given by the mouth, by retention enemas or by both at the same time. By the first route the daily dose is 4 grains, either in powder form in capsule or as keratine coated pills, given 3 or 4 times a day after meals for 10 days. It tends to cause diarrhoea and this according to Knowles appears to exert a beneficial action.

But chiniofon is more effective when given by rectum. When combined with E.B.I., as it often is, it is best given in the morning, otherwise at night. The lower bowel is first washed out and cleared of mucus with a pint of 2 per cent sodium bicarbonate enema. One hour later 'the chiniofon retention enemas (2½ per cent solution in 7 oz. warm water) should be slowly run into the rectum with a no. 10 rubber catheter with the patient lying on his left side; when the solution has entered the rectum he should turn on his back for half an hour, and then on his right side, so as to facilitate percolation throughout the large intestine. The abdomen should be massaged anti-clockwise. The foot of the bed should be raised about a foot on blocks. Most patients can retain the solution for 8 hours' (Manson-Bahr, 1944). The treatment is given for ten consecutive days.

2. *Vioform or enterovioform*.—This drug differs from chiniofon in containing chlorine and considerably more iodine (38 per cent). It is given in gelatine capsules each containing 0.25 gm. (4 grains) of the powder, three times daily for 10 days, and can be repeated at ten-day intervals. It is contra-indicated if there is liver involvement.

3. *Diodoquin*.—This drug, much used in the U. S. A., seems to be only slightly toxic despite its high iodine content (64 per cent). The standard dosage is three tablets, 3.2 grains each, three times a day for 20 days. It does not produce the unpleasant purgation often experienced with the use of the other oxyquinoline derivatives when given orally. Morton (1945) found it very useful in cases in which, owing to inadequate treatment consisting of repeated courses of emetine injections, the entamœbæ appeared to have become temporarily emetine-fast. It is useful for the treatment of cyst passers and can be given concurrently with emetine injections in cases of amœbic hepatitis.

IV. Chemotherapeutic agents

In chronic cases secondary bacteria gain access to the bowel wall through the ulcerated mucosa and play a large part in rendering standard treatment inefficient. In several such

cases penicillin has been found to be remarkably effective. To combat some of the organisms which are not sensitive to penicillin a course of sulphasuxidine is also given concurrently by mouth; this sulphonamide is chosen owing to its low absorption and high concentration in the intestine. Both drugs have no effect on the amœbæ but make them more amenable to emetine and other specific drugs. Coghill (1945) suggests that they should be given in all cases of amœbic dysentery, fresh or old, on the suspicion that secondary infection has taken place and that they should be administered concurrently with emetine as well as before it. Their dosage and methods of administration will be given later.

V. Miscellaneous

1. *Kurchi and derivatives*: (a) *Kurchi bark* (containing an alkaloid, *conessine*).—Sixty grains of the bark in the form of tablets of 1 to 2 drachms of the extract are given orally every day for a lengthy period as an after-treatment in chronic cases.

(b) *Kurchi bismuth iodide* (K.B.I.).—It contains the total alkaloids of the bark and is given in doses of 10 grains twice daily for 10 to 20 days, preceded half an hour before by a mixture containing $\frac{1}{2}$ drachm of sodium bicarbonate and sodium citrate each.

Kurchi is a non-toxic drug and has been known to control the symptoms and keep the patient in good health when other drugs have failed. In an analysis of the results of treatment with various drugs Knowles *et al.* (1928) found the ratio of probable cures to failures from kurchi as 1:1.1 in a series of 16 cases while Chaudhuri and Rai Chaudhuri (1946) found still better results (1:0.8) in a large series of 188 cases. But in the last war reports on this drug have been unfavourable. However, as Chopra (1936) pointed out, these discordant results may be due as far as kurchi-bismuth-iodide is concerned to (1) faulty procedure in the extraction of the alkaloids and (2) use of immature, improperly collected and imperfectly dried bark. So before condemning the drug it is worth enquiring into these details.

2. *Bismuth*.—The subnitrate or the oxycarbonate in large doses has been advocated by some clinicians. It has a low amœbicidal activity and to-day its use is confined more for symptomatic relief, *e.g.* excessive frequency of stool than for any specific action against the infection. It may also be used during convalescence if the diarrhoea persists.

Toxic effects

In large doses, more than 1 grain a day, emetine has a general toxic action on the tissues, with a special affinity for the heart, and may cause unpleasant and serious symptoms such as nausea and vomiting, depression and debility, cardiac weakness and irregularity, and

fall of blood pressure. It is specially toxic to women and children. Sometimes the diarrhoea actually increases. Degenerative changes appear in the heart after excessive doses, and hence are more commonly seen in relapsed cases who have had previous courses. Formerly, these untoward effects were put down to the disease itself, and a diagnosis of post-dysenteric heart failure or weakness was not uncommon. It is probable that personal idiosyncrasy plays a part in some cases. In rare cases emetine leads to myositis and even neuritis which may produce partial paralysis. Manson-Bahr (1945) has seen atrophy of scapulo-humeral group of muscles, resembling chronic poliomyelitis. Sometimes emetine has curious effects on the nails, causing ridging and great enlargement of the lunule. The myocardial damage may be missed if the pulse is examined only when the patient is at rest; a little exercise, even the erect position alone, may quicken up the rate enormously. Mild cases clear up in a few weeks, but in others the symptoms may persist for months or even longer. But on the whole its employment is not dangerous provided the patient is kept in bed and heroic doses and repeated courses are avoided.

Arsenicals.—The toxic effects may appear in the form of abdominal distress, nausea and vomiting. Stovarsol may give rise to erythema with pyrexia and even to exfoliative dermatitis. A delayed papular rash has sometimes appeared two or three weeks after the administration of the drug. Carbarsone is a much safer drug. These drugs should be withdrawn in patients who experience gastro-intestinal irritation, visual disturbances, jaundice and skin eruptions.

Oxyquinoline derivatives.—Toxic symptoms are much less common with these drugs except occasional abdominal pain, diarrhoea and headache. Podoquin has caused pruritis ani in a few cases.

(To be concluded)

HOWARDS & SONS LTD. (Est. 1797) ILFORD, LONDON.

VIROL

in the treatment of debility

The composition of Virol is such that it satisfies all the most important dietetic requirements in the treatment of debility, whether the debility is due to illness or to other causes.

Virol provides an ample calorific intake of carbohydrates, protein, and fat, accompanied by an adequate supply of the other essential nutritive factors. It is readily assimilated and completely absorbed by even the most delicate digestive system, without risk of strain. Virol is pleasant in

flavour. The patient takes it with relish and benefits not only by its direct nutriment, but also because it assists in the digestion of other foods.

The value of Virol in debility and wasting conditions has been demonstrated by over forty years' clinical experience and by its increasing use in Hospitals and Clinics.

VIROL is composed of MALT EXTRACT, ANIMAL FATS (*specially refined*), EGGS, SUGARS (*including Glucose*), ORANGE JUICE and added mineral salts and vitamins

B.D.H. ŒSTROGENS

In the Treatment of the Menopausal Syndrome

The use of œstrogens for the control of menopausal symptoms is an established practice, the choice of œstrogen being the responsibility of the practitioner in each individual case. The following B.D.H. œstrogens are available :—

OESTROFORM

Oestroform is the most generally satisfactory preparation for menopausal patients. Treatment is by means of injection; therefore it is completely under the control of the physician. The subjective manifestations of the climacteric appear to be more effectively controlled with œstroform than with the synthetic œstrogens.

STILBOESTROL B.D.H.

Stilboestrol is the most widely used synthetic œstrogen. It is effective orally but may produce nausea in a few patients.

DIENOESTROL B.D.H.

Dienoestrol is therapeutically similar to stilboestrol with the advantage that it does not cause any nausea even in susceptible patients.

Stocks of B.D.H. œstrogens are held by leading chemists, and full particulars are obtainable from—

WATSON 'MX-2' X-RAY APPARATUS

The portable with the big performance

Compact and easily dismantled, Type MX-2 has the power for a wide range of radiographic procedures.

The rating is 80 kVp. at 15 mA; it has a generous screening rating, mains compensator, kilovoltage and mA controls and a 12 second timeswitch.

Type "MX-2" was adopted as the standard portable by the Army Medical Services and is particularly well suited to strenuous use in remote regions, the shockproof tube head being sturdy and immune to atmospheric conditions.

Delivery can at present be made from stock; write for literature to Watson & Sons, manufacturers of the officially adopted apparatus for Mass Miniature Radiography.

APRIL

HOMOLOGOUS SERUM JAUNDICE

THE identity of this disease has been established during the last 10 years. The term homologous applied to the serum indicates merely that it is derived from the same species. There is no suggestion in it of its isohæmagglutinin content. *Iso*serum would be better than *homologous* serum.

(The term homologous itself, applied to a *specific* serum in immunology, is not used in the correct biological sense. The wing of a bat or even the wing of a bird is *homologous* to the arm of a man. The clitoris is homologous to the glans penis. The wing of a bird, on the other hand, is only *analogous* to the wing of a housefly. Homology is an affinity between developmentally related structures which look dissimilar as opposed to analogy which is a resemblance in appearance and function only.)

The term jaundice is rather euphemistic. The morbid state arising from the parenteral entry of an isoserum is a serious form of hepatitis and much more likely to prove fatal than the 'catarrhal jaundice' of convenience.

The available evidence suggests that the causative agent, probably a virus, is not the same as that causing the naturally occurring infective hepatitis (MacCallum, 1946).

The jaundice transmitted by syringes, the late hepatitis following injection of any therapeutic agent, is identical with homologous serum jaundice and is communicated by traces of blood transferred on syringes and needles from man to man (Memorandum, 1945).

Cases in children attracted attention in the beginning.—In 1937, 4 children died in or near Oxford, after receiving injections from a single batch of measles convalescent serum, nine or ten weeks previously. Eventually 109 recipients of the serum were traced, 41 had been ill subsequently, 37 of them with jaundice. Eight had died of hepatic necrosis. All deaths had occurred between the 61st and 93rd day after receiving the injection (MacNatty, quoted by Bradley, 1946).

Cases in adults attracted attention later.—The American troops receiving *yellow fever vaccine* developed jaundice. This was not due to the yellow fever virus but to the human serum used as a vehicle of the virus (Findlay, 1940, quoted by Bradley, loc. cit.). The icterogenicity was confined to certain batches of the vaccine with adjacent serial numbers.

Mumps serum jaundice attracted attention in England. In a unit of a British Tank Corps two batches of pooled serum, from 11 convalescent

cases, were given to 260 cases once and to 204 of the same men twice at 14 days' interval. Two hundred and twenty men were followed up. 44.7 per cent developed jaundice 44 to 123 days later (Beeson et al., 1944).

Pappataci vaccine jaundice was noticed in Southern Russia. The active virus had been mixed with convalescent human serum.

Jaundice after blood, plasma or serum transfusion has been noticed in England in many cases, 2 to 4 months after the transfusion. Deaths have occurred from hepatitis. No previous treatment of the whole blood plasma or serum appears to be effective in preventing the disease (MacCallum, loc. cit.). Very small quantities of serum (0.01 c.c.) can infect.

The natural communicability of the disease, if it be naturally communicable at all, is of a very low order. The incubation period is very long, of the order of months (Bradley, loc. cit.).

Similar disease in animals.—Jaundice with mad staggers has been reported in horses after immunization with antigens administered in horse serum (Theiler, Gordon, March and Slagsvold, quoted by Bradley, loc. cit.).

Treatment.—Two apparently hopeless cases of serum hepatitis have been treated successfully with protein hydrolysates intravenous 'alimentation' (500 c.c., equivalent of 25 grammes protein, preceded by 500 c.c. of 5 to 10 per cent glucose) for several days (Simon and Brown, 1946; Magee, 1946). Large doses of methionine (2.5 to 3 grammes orally) have also been found useful (Beattie and Marshall, 1944a; Beattie and Marshall, 1944b; Beattie, 1946). This drug, however, has not been found useful in the impairment of liver function by other workers (Cook and Hoffbauer, 1946).

A new risk in blood transfusion.—In blood transfusion to the usual risks—incompatibility of the red blood cells and sera, syphilis and malaria—must be added the new risk of the homologous serum hepatitis. As a safeguard it has been naturally suggested that the donor should not have suffered from jaundice (Snyder, 1947). This precaution will exclude all previous sufferers from jaundice including those who might have suffered from the variety which on inoculation into other subjects might give rise to the homologous serum jaundice. But it has not been established that the donors of the sera which did give rise to the disease had suffered from jaundice.

Substitutes for transfusion.—Perhaps the protein hydrolysates could replace plasma and serum for most cases needing a transfusion. The compatible red blood cells washed free of the serum in saline could be used for the whole blood, if the virus is found in the serum only. As a matter of fact the preserved blood used in the World War I consisted of preserved red blood cells only (Wiener, 1943).

The serum can be eliminated by dilution with a large quantity of saline of a small quantity of whole blood. The settled cells can be separated,

re-suspended in another large volume of saline and allowed to settle a second time. If the supernatant fluid after the second settlement does not react with a strong antihuman serum, the chances of any serum being left after a third settlement are negligible. The average antihuman serum used for medicolegal purposes in India detects the human serum in a dilution of 1 in 40,000 (Greval and Chowdhury, 1947). A stronger antiserum can be prepared for the purpose. A possible diffusion of the contents of the red cells into the saline will not interfere by giving a false positive reaction. This material does not react with the antiserum prepared against the serum (Greval and Chowdhury, 1945).

Only human serum albumen may be used. This derivative has been reported to be free from the ieterogenic agent (Climenko, 1947).

Special selection of donors.—When a real whole blood transfusion is considered absolutely necessary, members of the same family, community and locality (in this order) are likely to provide safer donors than total strangers. The history of the former is better known, and because of a similar environment, the recipient and the donor are likely to have a similar immunological constitution.

No Indian cases.—Post-transfusion homologous serum jaundice has not attracted attention in India yet. The Calcutta Blood Bank provided blood and serum for 6,762 transfusions during 1945, 1946, and a part of 1947, mostly to hospitals, and did not receive a single report of a recipient developing jaundice after a month or so (Chatterji, 1947, personal communication). It is quite possible that the disease, like many other European diseases, does not thrive on Indian soil (Greval, 1946).

A re-estimation of the utility of blood and blood production.—The use of convalescent serum for children cannot be considered safe any longer in Europe at any rate. Measles could not have killed as many children at Oxford as were killed by the serum.

The utility of transfusion, in civil practice, also needs a reconsideration. It should be differentiated from a mere boost. Such a boost in the transfusion of whole blood has been suspected and discouraged (Albrecht, 1946). It should be discouraged in the transfusions of other constituents of blood also.

THE DANGERS OF EXCLUDED INTESTINAL SEGMENTS

Loops of intestine, by-passed or excluded for one reason or another, are subject to certain acute accidents which, if not remembered and provided for, may vitiate an otherwise satisfactory operation. The naturally excluded loops—the appendix and Meckel's diverticulum—are no exceptions to this rule. The acute accidents common to these loops, natural or artificial, are intussusception and perforation.

Intussusception of the appendix was first reported in 1859 by McKidd, since when about one hundred cases have been reported in the literature. What proportion of the total number observed this figure represents is unknown, but it must be less than half for by far the greater number of members of the profession are distinctly reluctant to publish their interesting cases. Meckel's diverticulum is mentioned as a cause of intussusception many times between the date of its discovery, at the beginning of the nineteenth century, and 1913, when Wellington collected 326 cases of urgent surgical conditions arising in this remnant. Among these were 144 cases of bowel obstruction, 59 of which were due to intussusception of a Meckel's diverticulum.

Experimentally, Nothnagel (1884) produced intussusception by direct faradic stimulation of the intestine. Propping (1910), using rabbits and large doses of physostigmine, was able to cause small invaginations of the gut. All experimental workers using dogs are familiar with the fact that intussusception will occur following severance and inversion of the ends of the upper small intestine unless the precaution is taken of fixing the distal segment to the anterior or posterior wall of the abdomen.

Perforation of the appendix and of Meckel's diverticulum are well known. But the possibility of perforation of an excluded segment seems to be often forgotten. The dangers of leaving such

excluded segments in the abdomen were pointed out by Grey-Turner (1916), when he cited some of his own cases in illustration.

Experimentally, it is easy to produce perforation by excluding the proximal loop instead of the distal one.

In view of these facts it is well worth while remembering at the operation table what a few more minutes and several anchoring sutures will do towards making a final success of a procedure. It is well to consider any operative plan, made hurriedly to meet unforeseen circumstances, in the light of these facts before embarking on a line of action which may lead to the

exclusion of a distal or proximal segment of intestine.

An article in this connection is appearing on p. 203 of this issue.

Medical News

FORMATION OF WORLD HEALTH ORGANIZATION

(Abstracted from the *Medical Press*, 28th August, 1946, p. 159)

THE Economic and Social Council of the United Nations, by a resolution of 15th February, 1946, convened an International Health Conference to establish an International Health Organization. The International Health Conference met in the City of New York from 19th June to 22nd July, 1946. More than fifty countries sent representatives, and seventeen States were represented by observers. The Conference drew up and signed the Constitution of the World Health Organization, an arrangement for the establishment of an Interim Commission of the World Health Organization, and a Protocol Concerning the *Office International d'Hygiene Publique*. At the same time, steps were taken to transfer to the new Health Organization such health functions as had been formerly carried out by the League of Nations Health Organization.

THE FOURTH INTERNATIONAL CANCER RESEARCH CONGRESS

THE Fourth International Cancer Research Congress will be held in St. Louis, Missouri, U.S.A., during 2nd to 7th September, 1947. The Union Internationale Contre le Cancer having accepted the invitation of the American Association for Cancer Research, the Congress will be held under the joint auspices of these two organizations, with Dr. E. V. Cowdry, Professor of Anatomy, Washington University School of Medicine and Director of Research of the Barnard Free Skin and Cancer Hospital, serving as President of the Congress.

Of the three Congresses that have been held previously, the first was in Madrid, Spain, in 1933; the second in Brussels, Belgium, in 1936; the third in Atlantic City, New Jersey, U.S.A., in 1939. Due to the recent war, there has been no meeting of the Congress during the past eight years.

The State Department in Washington having approved of the International Cancer Research Congress, official invitations soon will be sent to all foreign governments who are to send delegates.

Initial steps in the organization of the Congress have been completed, in that all officers and committees have been appointed and are enthusiastically at work. In addition to the President, Dr. E. V. Cowdry, Dr. J. Godard, President of the Union Internationale Contre le Cancer, and Dr. W. U. Gardner, President of the American Association of Cancer Research, will serve ex-officio as members of the Executive Committee.

The following Committee personnel have accepted Chairmanships:—

- A. N. Arneson, St. Louis, Missouri—Local Arrangements.
 S. Bayne-Jones, New Haven, Connecticut—Finance.
 C. W. Larimore, New York, N.Y.—Exhibits.
 L. A. Scheele, Bethesda, Maryland—Governmental Liaison.
 M. G. Seelig, St. Louis, Missouri—Publicity.
 Shields Warren, Boston, Massachusetts—Programme.
 Headquarters will be at the Hotel Jefferson, St. Louis, where some three hundred rooms will be available for guests. In addition to these rooms, other nearby St. Louis hotels have signified their willingness to make reservations on advance notice to make contemplating attendance at the Congress.

THIRTEENTH CLINICAL MEETING OF THE CALCUTTA SCHOOL OF TROPICAL MEDICINE HELD ON MONDAY THE 13TH JANUARY, 1947

DR. DHARMENDRA showed three cases of leprosy of the lepromatous type in whom the disease had remained subsided for two to five years. In the beginning the cases had fairly extensive lesions typical of the lepromatous type; at the time of demonstration, however, there were practically no visible signs of the disease. The lesions had gradually subsided and faded, and the smears once strongly positive for leprosy bacilli became less and less strongly positive, and ultimately negative and had remained negative. The cases were presented to illustrate a little-appreciated feature in the course of leprosy; it is not often that the disease, even in the lepromatous type of cases, may show early subsidence, and may not become progressively worse.

Dr. Chettri described a case of typhus which appeared clinically one of scrub typhus but the agglutination test was not of diagnostic titre.

Major A. L. Som demonstrated a case of posterior extra-articular scapulo-humeral arthrodesis with an arrow graft from tibia (Britton's technique). Recent x-ray showed that the graft was living. It was a case of old fracture dislocation of the upper end of right humerus with axillary palsy. Shoulder joint movements were very limited and painful. Now the patient can raise his right upper limb up to 90° abduction, can take food with right hand, and can perform light duties.

Dr. H. Ray demonstrated a case of chronic advanced gout. The patient was a Mohammedan male, aged about 35 years, and was a cultivator by occupation. No history of any alcoholism or overeating of food rich in nucleoproteins was available. Family history irrelevant. The condition started in the left tarsus

following a sprain 12 years ago as an acute arthritis. Since then several recurrences took place gradually involving multiple, big and small, joints of the limbs. At the time of demonstration, gross deformity of the hands and feet with limitation of movements was obvious. Multiple tophi, some cutaneous and some subcutaneous, were present. Material from one such tophus examined microscopically revealed acid sodium urate crystals. A skiagram of the hand revealed scattered areas of bone absorption; osteophytic growths from the bone ends, narrowing and at places osseous bridging of the joint spaces and a pathological fracture of one of the phalanges. Blood uric acid was 8 mg. per 100 c.c. Refractoriness of the case to usual lines of treatment was pointed out.

Dr. Hafizur Rahman showed one case of thyroglossal fistula. This was a complete fistula from the foramen cæcum to middle of the thyroid cartilage where it opened up. He also showed a case of congenital dislocation of right hip in a child of 18 months. The trouble was noticed by the parents as the child did not try to stand up at the right age.

Dr. N. V. Bhaduri discussed the treatment of intestinal worms with the indigenous drugs, Butea, Embelia and Kamala. Due to the want of imported anthelmintics during the last war, the indigenous drugs, Butea, Embelia and Kamala were tried in hookworm, *Ascaris*, *Trinia* and *Hymenolepis* infestations of man. These drugs were found to have no effect on hookworm and tapeworm. In *Ascaris* infestations, Butea and Embelia were found better than santonin and equally as good as oil of chenopodium. Comparative results and dosages are given below:

Drug	Dose in grains	Number treated	Number cured	Percentage
Butea	8-30	24	4	16.6
	60-120	12	8	66.6
Embelia	30	2	0	Nil
	60-180	10	4	40
Combined Butea and Embelia ..	10-45	135	24	18
	60-180	97	47	48
Combined Butea, Embelia and Kamala.	10-30	19	2	10.5
	60	6	3	50
Santonin	3	90	31	33
Oil of chenopodium	1.5 c.c.	67	37	55

These indigenous drugs are cheaper than santonin and oil of chenopodium. Two drachms of either Butea or Embelia cost less than one pice while one 3-grain dose of santonin costs three annas and a dose of oil of chenopodium (1.5 c.c.) costs about two annas.

Dr. D. N. Roy described briefly the different methods of 'delousing' in connection with head and pubic lice. The two most successful preparations for head lice are pyrethrum extract and phenyl cellosolve (monophenyl ether of ethylene glycol). Pyrethrum extract is prepared with kerosene and sprayed by means of a De Vilbiss atomiser no. 15 on every part of the hair. The insecticide is then rubbed in the hair in order to ensure uniform distribution of the oil globules. Phenyl cellosolve mixture is prepared with absolute alcohol and water in a 5 per cent strength and applied to the hair by means of a wad of cotton-wool, sufficient quantity being used to wet the hair thoroughly. Both the preparations are effective in destroying all stages of lice including eggs. D.D.T. acts on lice but not on eggs. As regards pubic lice, infestation of all parts of the body except the eyelashes may be treated with either of the above preparations. Pubic lice on eyelashes are killed by pyrethrum ointment prepared with the dust in 8 per cent strength and applied locally for four nights in succession.

'COLLEGE OF PHYSICIANS AND SURGEONS OF BOMBAY'

INSTITUTION OF POST-GRADUATE DIPLOMAS IN VARIOUS SUBJECTS

The Council of the College of Physicians and Surgeons of Bombay at its meeting held in January 1947, decided to institute Post-graduate Diplomas in the following subjects:—

- (1) Dermatology and Venereology.
- (2) Oto-Rhino-Laryngology.
- (3) Orthopædics.
- (4) Anæsthetics.
- (5) Radiology.
- (6) Anatomy.
- (7) Physiology.

The regulations relating to these diploma examinations are under preparation.

COLLEGE OF NURSING IN INDIA

(Abstracted from the *Science and Culture*, Vol. XII, No. 4, October 1946, p. 187)

INADEQUACY of Health Personnel in India is emphasized in the 'Report of the Health Survey and Development Committee, 1946'. It has been estimated that the number of registered nurses available in India at present is 7,000, i.e. 1 nurse to every 43,000 people. The Bhoré Committee has recommended that the number of trained nurses available in the country should be raised to 740,000 by 1971, i.e. 1 nurse to every 300 people (this is the ratio existing in the United

Kingdom). An essential step towards the achievement of this object is the removal of the existing unsatisfactory condition of training and service.

We welcome the establishment of the 'first nursing college in India' and we hope that more colleges will be established in every province so that it may at least be possible to reach the target fixed for the short-term ten-year programme, i.e. 80,000 nurses without delay. To raise the number of nurses to 80,000 in ten years is not simple and the establishment of specialized hospitals and schools of nurses is the immediate problem and more so for the fact that the need for nurses is even greater than that for doctors.

The College which opens this year as a constituent part of Delhi University offers a four-year preparatory course which will integrate the teaching of health and preventive medicine throughout the entire course. It will prepare nurses to give good nursing care in the homes of both urban and rural areas, as well as in the hospital. Other colleges and the hospitals of Delhi are co-operating in the course and it will lead to the degree of B.Sc. (Honours) Nursing.

The College is located at 12, Jaswant Singh Road, New Delhi. The course of study is given below in order to draw the attention of readers and responsible leaders of opinion to encourage Indian girls to join the

course. No doubt other universities will initiate such a course if the demand for it increases.

The College provides a course for the B.Sc. (Honours) Nursing of the Delhi University. The course of study extends over a period of four academic years. The Honours course includes the following subjects:—

- (a) Main subject—Nursing.
- (b) Two subsidiary subjects:
 - (i) English;
 - (ii) Elementary Science (Physics, Chemistry and Biology).
- (c) Any one of the following qualifying subjects:
 - (i) History of Science and Scientific method;
 - (ii) World History;
 - (iii) Modern Indian History.

The minimum qualification for candidates desiring admission to the course is:—

- (i) The Higher Secondary Examination of the Board of Higher Secondary Education, Delhi, or any examination recognized as equivalent thereto, or the London Matriculation Examination or the Cambridge (Senior) School Certificate Examination or the Oxford School Certificate Examination, or
- (ii) The Qualifying Examination conducted by the University of Delhi, or
- (iii) The Intermediate Examination of any Indian University incorporated by any law for the time being in force, or any examination recognized as equivalent thereto.

The College Session commences on the 25th July, and applications for admission should be submitted by 30th June on forms that can be obtained from the Principal.

IMPORT LICENCES UNDER DRUGS RULES

(Reproduced from a press note dated 1st March, 1947, issued by the Government of India, Department of Health, New Delhi)

UNDER the Drugs Rules, 1945, which come into effect from 1st April, 1947, licences are necessary for the import of biological and other special products intended for sale and of products intended for examination, test or analysis.

Owing to printing delays it has not been possible to make available to the trade printed copies of forms of application prescribed for the purpose under the Rules. Pending availability of printed forms, importers should submit typed applications in the prescribed forms to the Drugs Controller, c/o Director-General, Indian Medical Service, New Delhi.

Where fees have been prescribed under the Rules, the applications are to be accompanied by a treasury receipt.

HISTORICAL ASPECTS OF TUBERCULOSIS

'THE history of tuberculosis can be defined as the history of civilization itself', observed Lieut.-Colonel R. Viswanathan, T.B. Adviser to the Health Department, Government of India, speaking on 'Historical Aspects of Tuberculosis' at the Delhi University recently.

He said that there was evidence of tuberculosis of bones and joints even in the pre-historic man of the Neolithic era.

In ancient India during the period of Rigveda there is a hymn consecrated to the cure of *Yakshama*, which is nothing else than what is now called tuberculosis. The laws of Manu lay down certain preventive measures including objections to marriages with tuberculous patients. The writings of Susruta contain cures for the disease, apart from prescribing early morning fresh air, horse riding and good food.

The old books of China speak of lung cough and lung fever known in Chinese as 'Laoping'. The remains of Egyptian mummies show definite evidence of tuberculosis, while the fire-worshippers of Persia, the Hebrews of Judea and the subjects of Alexander the

Great were well acquainted with the ravages of the disease. Hippocrates, father of Greek medicine, described for the first time the real symptoms of the disease and applied to it the name of *Pthylisis*.

While for nearly 15 centuries after Christ there was little advance in medical science in Christendom, Arabia made rapid advances during the 7th, 8th and 9th centuries. Rhazes (850-923) and Avicenna (980-1037) searched for cause and cure of diseases. The latter wrote on the subject of tuberculosis and prescribed dry air and sugar distilled from grapes as remedies.

Developments in modern times

Further researches were made during the period 15th to 18th century when scientists in different countries began to take greater interest in the disease and described its symptoms and prescribed remedies. In the 18th century Richard Martin, an Englishman, published his book called *Pthysilogia* which gave a good clinical description of the disease.

Coming to more modern times, Colonel Viswanathan said that Laennec (1781-1826) laid the foundation for the present-day knowledge about the pathology of pulmonary tuberculosis. After performing a thousand post mortems he published a paper in which he said that tuberculosis affected not only the lungs but other organs as well. He also invented the first stethoscope.

In the 19th century Bodington advocated for the first time sanitarium treatment. He was laughed at when he made the suggestion but it was taken up in Germany by Dr. Brehmer who started the first sanitarium in the world. Since then the sanitarium idea has spread to different countries.

In 1882 Robert Koch discovered the tubercle bacillus, the germ which is the cause of the disease. The next important milestone was the discovery of x-rays by Röntgen in 1895. A definite advance in the treatment of the disease was made by the introduction of artificial pneumothorax therapy by Carlo-Forlanini. Since then various surgical procedures have been adopted with the main object of collapsing the diseased organ which will enable it to be at rest.

Tuberculosis was tackled for the first time as a community disease when Sir Robert Phillip initiated the dispensary scheme in 1887.

Concluding, Colonel Viswanathan said that the discovery of certain antibiotic drugs like streptomycin acts as a pointer to the possibility of producing a drug which can be used as a specific for tuberculosis.

MATERNAL AND INFANT MORTALITY IN U.S.A.

INFANT mortality declined further in 1946 from the low rate for 1945, announces the U.S. Public Health Service, Federal Security Agency. Provisional figures for the first 10 months of 1946 indicate a decrease of 3.2 per cent from the rate for the same period of 1945.

Final figures for 1945 released at this time show that the infant mortality rate of 38.3 deaths under 1 year per 1,000 live births was the lowest ever recorded for the United States. It is 3.8 per cent lower than the rate of 39.8 for 1944. Infant deaths numbered 104,684 in 1945 as compared with 1944 when there were 111,127 deaths under 1 year.

The maternal mortality rate of 2.1 per 1,000 live births for 1945 also showed a reduction of nearly 9 per cent from the rate of 2.3 for the previous year. The numbers of deaths from puerperal causes on which the maternal mortality rates are based were 5,668 and 6,369, respectively, for 1945 and 1944.

One of the factors contributing to the lower infant and maternal mortality rates is an increase from 1944 to 1945 in the proportion of babies delivered in hospitals. In 1945, 78.8 per cent of all births registered in the United States were reported to have occurred in hospitals or other institutions. This represents an increase of 3.2 per cent from 1944 when 75.6 of recorded births took place in hospitals.

The attached table presents infant mortality rates by State of residence for the years 1944 and 1945. For twenty-eight States the rates for 1945 were below the rate for the United States. In general, low infant mortality rates indicate effective programmes of medical and nursing care for mothers and infants, of communicable disease control, and environmental sanitation. Because infant mortality rates are usually lower for white populations than for non-white groups the rates vary from State to State with differences in the racial composition of the population. Incomplete registration of births as well as infant deaths are extrinsic factors which influence infant mortality rates. The effect of the former is to raise the rate above its true value, while incomplete registration of infant deaths has the opposite effect.

Infant mortality rates for 1945 and 1944: United States and each State (exclusive of still births. By place of residence)

Area	Infant mortality rate per 1,000 live births	
	1945	1944
United States	38.3	39.8
Alabama	14.7	45.5
Arizona	68.7	68.8
Arkansas	31.7	34.7
California	32.5	34.5
Colorado	50.3	49.4
Connecticut	29.9	30.7
Delaware	38.9	48.7
District of Columbia	48.3	44.8
Florida	43.8	45.5
Georgia	42.2	44.5
Idaho	35.0	34.0
Illinois	31.6	32.4
Indiana	36.0	34.5
Iowa	30.3	33.1
Kansas	33.0	33.3
Kentucky	46.9	46.7
Louisiana	43.0	46.3
Maine	46.3	46.7
Maryland	38.0	41.5
Massachusetts	31.6	33.1
Michigan	35.8	37.9
Minnesota	31.3	31.3
Mississippi	40.6	44.1
Missouri	37.5	37.6
Montana	34.2	36.1
Nebraska	28.2	33.0
Nevada	46.3	50.2
New Hampshire	36.3	37.7
New Jersey	32.0	34.0
New Mexico	100.8	89.1
New York	31.8	32.8
North Carolina	43.3	45.4
North Dakota	29.3	35.4
Ohio	36.5	38.5
Oklahoma	40.0	41.2
Oregon	28.7	30.5
Pennsylvania	37.9	40.0
Rhode Island	28.2	35.3
South Carolina	49.9	54.9
South Dakota	31.1	34.9
Tennessee	47.7	45.5
Texas	48.8	50.4
Utah	31.1	33.9
Vermont	34.6	40.6
Virginia	47.4	47.1
Washington	34.5	33.8
West Virginia	52.0	52.0
Wisconsin	31.1	32.0
Wyoming	40.0	41.2

GERMAN 'PHASE' MICROSCOPE MAY AID CANCER RESEARCH

(Abstracted from the *Journal of the American Medical Association*, 20th July, 1946, p. 1010)

A SO-CALLED 'phase' microscope, obtained recently in Germany by army scientists, has been tested here and may be of use in studying how a normal, healthy cell changes into the deadly cancer cell. A film was made with the phase microscope by Bureau of Standards physicists and biologists and it showed cell reproduction with amazing clarity. With special lenses the phase microscope accents enormously slight optical differences.

UNUSUAL NURSING SERVICE: AUSTRALIAN SISTERS' SUCCESS

By MARGARET LAWRENCE

(From Release No. MNL/112 issued by the Public Relations Officer, Australian High Commissioner's Office, Australia Office, Connaught Place, New Delhi)

AN unusual form of nursing service, with definite possibilities, is the suburban surgical dressing station recently opened by three Australian nurses in Melbourne (Victoria).

The girls' mother—also a trained nurse—is elderly and a semi-invalid, and they were anxious to devote more time to looking after her and to housekeeping than would be possible if they were working full-time in hospital wards.

Threshing out their problems at a round table family conference, the girls decided there was no regular form of nursing service that would suit their case—so they invented one!

The idea of a suburban dressing station, where dressings could be changed, injections given, minor ailments treated by trained nurses, and minor operations performed by doctors, seemed to offer the girls a chance of following their profession in their own home.

Their experience in public and private hospitals convinced them that a real need existed for decentralization of hospital facilities, and that a surgical dressing station such as they envisaged might, even though on a very small scale, point the way to such decentralization.

Most of Melbourne's great public hospitals are situated in or near the city, so that the provision of such a station would save many sick and elderly patients a long and tiring journey, often followed by a long wait in the out-patient's clinic.

The girls' experience of hospital wards had shown them how often the doctor's time is taken up with minor treatments, well within the capabilities of a trained nurse. So the station would help to relieve the pressure on overworked doctors.

Similarly, by providing an operating theatre where visiting doctors could perform minor operations, and a recovery room where patients could rest for a few hours, the station would relieve the pressure on the beds of private hospitals.

Doctors, nursing authorities, medical superintendents and almshouses at public hospitals whom the girls consulted warmly supported their plan. Local doctors welcomed the establishment of the station, and gladly promised to send suitable cases for treatment.

The plan decided upon, the next step was to transform three rooms of an ordinary small bungalow home into a waiting room, rest or recovery room and surgery. The sisters proved themselves just as handy with kalsomine and paint brush as with a roll of lint and a thermometer.

Their gleaming whitewalled surgery is equipped with operating table, and apparatus, basins, instruments, linen, lotions, bandages and everything that would normally be found in the operating room of a small country hospital.

Total cost of transforming and equipping the three rooms—thanks to natural ingenuity and the purchase of secondhand hospital furniture—was Rs. 2,142.

Public Health Section

A TENTATIVE HEALTH AND HYGIENE PROGRAMME FOR RAILWAY SCHOOLS IN INDIA

By A. W. J. MORGAN, M.R.C.S., L.R.C.P.,
D.P.H., F.R.S.T.M. & H.

Chief Medical Officer
Bengal Nagpur Railway

SCHOOL health and hygiene schemes are well known in America and England, and while considerable progress has been made in various parts of India regarding the medical inspection of children of school age, it is felt that a preliminary report on a scheme in a controlled group of railway schools should be of interest to those who are concerned in the development of this branch of hygiene.

This preliminary report covers twelve months' working from 1st July, 1945 to 30th June, 1946; and without going into the details of the budget, it may be stated that the cost of the scheme amounts approximately to Rs. 8 per child per annum. It has, however, been worked out that if all the schools on the B. N. Railway are eventually included in the scheme, the cost may be reduced to Rs. 5. It may be of interest to know that the cost of similar schemes in the United Kingdom is 7 shillings and U.S.A. 1.5 dollars (pre-war).

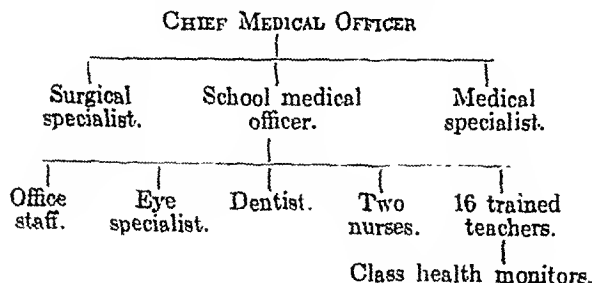

The details of the schools covered are as follows :—

Four schools have been taken up for work for a total strength of over 2,000 pupils :—

	Number of pupils
1. European High School	280
2. Indian High School	1,200
3. Indian Girls' School	276
4. Indian Primary School	302

The European school is a mixed school.

Organization and personnel

It was realized from the outset that it was essential to secure a suitable wholtime school medical officer who had a leaning towards this type of work and also in possession of a Diploma in Public Health. The services of one of such on a salary of Rs. 375-25-750 were secured. He works directly under the Chief

Medical Officer and is responsible for maintaining all the records.

To assist him in his duties there are two school nurses at Rs. 150 per month (fixed).

It was also essential to secure the intelligent co-operation of the school teachers. Although the syllabus for the normal training of teachers in India certainly contains instructions in school hygiene, it was felt that a further course of training would be very valuable. Suitable teachers were picked from the existing cadre and given an intensive practical and theoretical course. A curriculum was prepared, the first of its kind in India, for the training of 15 of our school teachers at the All-India Institute of Hygiene and Public Health, Calcutta. The course lasted three weeks and at the termination an examination was held. The teachers passed their examination and were given a certificate and their basic salary was enhanced by 10 per cent. The course was held during their vacation. and this leave will be made up to them when departmentally convenient.

The Railway Medical Department is fortunate in the fact that the Chief Medical Officer has at his disposal the following specialists : Surgical, Medical, Ophthalmic and Dental, so that defects could be referred to them for correction.

An important feature of the scheme was the attempt to interest and receive the co-operation of the parents. Each parent received a circular letter as follows :—

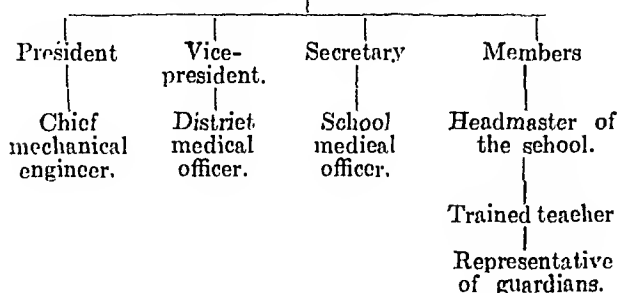

'A School Hygiene Scheme has been introduced in to the schools, and a school medical officer has been appointed by the railway administration solely for the railway schools here. He will examine your child or ward of class . . . free of charge on the . . . between . . . and . . . hours. It will be appreciated if you will please be present in the school when your child will be examined so that you may have an opportunity to tell the doctor anything about the child that he should know and that he may also give you useful advice about the child. This is very important, all the cases will be closely watched and followed up for the years the children will be in the school. I am sure you will be pleased to co-operate with us in making this very useful scheme a success in the interests of your wards reading in the school'.

Arising out of the interests of the parents are the staff conferences and the parent-teacher meetings. The staff conferences are separate for each school. These are held once a week to review the work of the past week, to draw up advance programmes and to discuss the difficulties. Members of the conferences are the trained teachers and nurses with the school medical officer as chairman. Forty-two such meetings have been held so far. Parent-teacher meetings serve the useful purpose of removing occasional obstacles in setting up the programmes, such as public lethargy, suspicion and ignorance of the parents. Each of the

trained teachers is contacting at least 5 parents in one week.

In order to further carry out effectively the programme and secure the co-operation of parents, a School Health Committee had to be set up :—

SCHOOL HEALTH COMMITTEE

There are two separate committees, one for the European school and the other for the Indian schools. These meetings are ordinarily held once a month.

Programme of the health work

1. School sanitation

The first step was a thorough survey of the sanitary position, particularly regarding buildings (air, light and ventilation), safe water supply, clean toilets and lavatories. During 1945, four schools were surveyed and the results of survey are given below :—

Schools with satisfactory structural condition, lighting, water supply and ventilation ..	4
" completely equipped with proper desks or benches ..	3
" with adequate playground facilities ..	3
" " required floor space per pupil ..	1
" " adequate latrine accommodation ..	1
" " separate accommodation for boys and girls ..	1
" " refuse baskets for each class ..	1

The plans for improvement have been submitted to the Engineering Department.

Periodic sanitary inspection of school premises and sanitary equipment is done by the school medical officer and nurse at least once a week.

Records are kept and brought before the committees.

2. Medical examination

(a) *Scheme of examination.*—This was commenced on 1st July and carried out in accordance with a previously drawn advance programme. The parents were informed of the initial medical examination and requested to attend (see circular above). On an average 6 to 7 children were examined per hour. Heights and weights were recorded, followed by complete physical examination of the child.

Defects observed were recorded on the prescribed form for each child. Specific notations used to signify the presence and severity of the defects are subsequently tabulated in the prescribed form. Parents are notified of

the results of the examination and the recommended course which should be adopted for relief.

(b) Results of examination.—

Name of school	Total examined	Number defective	Percentage defective	Total number of defects*
European	340	269	79	643
Indian ..	1,803	1,516	84	4,312

* There were approximately more than 2 defects per child, the percentage of defects being more in the Indian schools.

Nature of defects

1. *Malnutrition.*—(68.6 per cent of children examined).

The 'Nutrition Assessment Score Card' was used. The nutritional deficiencies were tabulated as slight, moderate and severe.

Comparative figures of malnutrition, Indian schools and European school :—

School	Total examined	WITH NUTRITIONAL DEFECTS	
		Total	Percentage
Indian	1,803	1,347	74.7
European	340	125	36.7

The deficiencies observed have been mainly due to lack of vitamins in their diets.

2. *Teeth and gums.*—(34.2 per cent).

The percentage of dental defects in Indian schools and European school was 31.9 per cent and 48.4 per cent respectively.

Broadly classifying the various types of dental defects were: Dental caries 84 per cent, tartar 8 per cent, bleeding gums 6 per cent and root abscess 2 per cent. To what extent dietetic errors were responsible for this high incidence it is difficult to say.

3. *Anæmia.*—(34.1 per cent).

It has not been as yet possible to commence routine laboratory examinations. In part, this anæmia was very likely due to causes other than nutritional, such as parasitic infestation.

4. *Enlarged glands.*—(18.4 per cent).

5. *Throat.*—(17.5 per cent).

The incidence of throat defects was fairly high, being more in the European school.

6. *Eyes.*—(11.0 per cent).

The majority of eye complaints was due to myopia, conjunctivitis, blepharitis and styas.

7. *Heart.*—(4.0 per cent).

Defects were organic, functional and nutritional. In 0.6 per cent (i.e. 14) organic lesions were detected due to rheumatic infections.

8. *Lung diseases.*—(0.7 per cent).

No tubercular lesions were detected clinically.

9. *Others*.—(41.6 per cent).

Uncleanliness constituted half of this group. Detected mainly amongst Indian school children who were also found to be ill-clothed and without shoes in the majority of cases. *Lousiness* and *scabies* formed the next major group.

Leprosy was detected in 7 cases during the routine examination. They were promptly excluded from the schools and referred to clinics for treatment. Non-infective cases, confirmed by the School of Tropical Medicine, Calcutta, were later on allowed to attend the school.

Immunization status

Vaccination against smallpox.—At the time of initial examination all the children were found with vaccination scars but there was no systematic record as to when the vaccination was done; so all the children were re-vaccinated. Records are kept of those vaccinated elsewhere.

The results of vaccination against smallpox have been classified as follows :—

	Per cent
(a) Those showing immune reaction ..	98.82
(b) " " accelerated reaction ..	0.41
(c) " " primary reaction ..	0.77

During the year under review only 4 cases of smallpox occurred among the children.

Correction of defects

The defects are tabulated in respective categories and corrected by making use of the existing facilities :—

1. *Central clinics*.—Held at the central place, office of the school medical officer, mainly on holidays and outside the school hours. One hundred and eighty-two minor cases have been treated.

2. *School clinics*.—Held within the school premises during school hours for the following conditions :—

(a) *Malnutrition*.—This is the biggest problem. However, a serious effort is made to combat it by giving the children, showing nutritional defects, multivitamin-cum-mineral tablets obtained from the American Friends Service Committee, on an average at the rate of 2 tablets per child daily for a period of three months. In most of the cases the course had to be repeated. In all, 1,417 children have been given multivitamin tablets.

For improvement of nutrition, a scheme is being formulated whereby each school child will be given 8 oz. of milk per day.

(b) *Scabies*, *malaria*, *ringworm*, *sore throat*, *conjunctivitis*, *ear affections*, *cuts* and *wounds*.

(c) *Delousing* is accomplished by thoroughly dusting the head for three consecutive days with 10 per cent powder of D.D.T. in soap stone. On the fourth day a thorough wash is given with soap and hot water. The result of the treatment has been very encouraging.

Figures for (b) and (c) are condensed in the table below :—

Treatment given in the school clinics

Diseases	European	Indian High	Indian Girls'	Indian Primary

7. Ringworm ..	1	4	1	..
8. Malaria	7	..	3
TOTAL ..	252	855	456	575

3. *Dental clinics*.—Held three times a week by a dentist.

(1) Number with dental defects ..	734
(2) Number corrected ..	435

To date, approximately 59 per cent of the cases have been corrected.

Number of children attended by dentist ..	435
Number of teeth attended by dentist ..	814

Nature of correction done :—

(1) Extractions ..	547
(2) Filling ..	67
(3) Lancing ..	64
(4) Scaling and gum treatment ..	136
TOTAL ..	814

4. *Eye clinics*.—An ophthalmic surgeon attends to the eye cases three times a week outside school hours.

Number of children with eye defects ..	257
Number attended by the eye specialist ..	220
Number with refractive errors ..	73
Number with eye diseases: ..	51
(1) Conjunctival diseases ..	34
(2) Squint ..	6
(3) Blepharitis ..	5
(4) Others ..	6

In the group of conjunctival diseases, chronic catarrhal conjunctivitis and trachoma were most common. Out of 73 cases of errors of refraction, 53 had glasses prescribed to them.

The surgical and medical specialists of Khargpur Hospitals helped (a) in aiding to confirm the diagnosis and (b) in the treatment of more serious and complicated cases. The local dispensaries are also available for the treatment of cases whenever referred.

Immediate information is given to the school medical officer regarding children sick at home and treated there.

Campaign for correction of defects does not end here, but careful watch is kept on the children given treatment. This is incorporated in 'Follow-up programme', i.e. children are followed up till and after the defect is corrected. It is applied in four circumstances:—

- (a) Children absent for 3 days or more.
- (b) Children excluded from school.
- (c) Children sick at home.
- (d) Children receiving treatment in the clinics.

In some cases this procedure necessitates home visits which are regularly done by the nurse, trained teachers and school medical officer, whenever necessary. In the table below is shown the number of cases followed up and the home visits paid:—

- (a) Number of cases followed up .. 1,276
- (b) Number of home visits .. 783
- (c) Monthly variation of the follow-up cases:—

July	1945	..	12
August	1945	..	33
September	1945	..	47

January	1946	..	180
February	1946	..	283
March	1946	..	175
April	1946	..	273
May	1946	..	39
June	1946	..	41

Health education

An attempt is made to inculcate into children a true knowledge of desirable habits. For this purpose, each class receives one hour of 'talk' or 'demonstration' on health every week by the trained teacher, nurse or the school medical officer. The teachers themselves are given such talks every month by the school medical officer. Health habit training booklets with twelve health commandments are being introduced.

Teachers' work

This work is done by the teachers, chiefly the trained ones, assisted by the monitors when necessary.

1. *Daily inspection.*—Commencing the day's work, each class parades and pupils are examined for obvious visible defects, i.e. lack of cleanliness, dirty nails, lousiness, etc. From here cases requiring treatment are referred to the school clinics. The class health monitors assist in daily inspection.

Name of school	Defects observed	Defects corrected	Per cent
European ..	1,233	1,203	97
Indian High ..	17,136	9,053	52
Indian Girls' ..	5,856	897	15
Indian Primary ..	16,420	11,125	67

2. Detection of absentees.—

Absentees	NAMES OF SCHOOLS			
	European	Indian High	Indian Girls'	Indian Primary
Total	1,179	22,029	1,311	2,748
Over 3 days ..	418	1,422	732	322
Due to disease ..	184	336	134	112
Followed up ..	206	131	95	133
Excluded ..	42	785	43	59

Unless a definite record is kept, it is very difficult to reduce the number of absentees.

The teachers also participate in home visits, follow-up, and health education.

Other work has also been taken in hand, such as training of the nurses and teachers.

Conclusion

Properly planned school health services are most essential in this country as the figures have borne out. Recently, in July, the scheme has been extended to include Adra, and it has brought a further 1,400 children under our care.

The first year's working reveals, in bold relief, the poor nutritional state of the school children, both European and Indian, in this country. Our work has shown that 79 per cent of the European children and 84 per cent of the Indian children showed signs of defects, and that with the use of the 'Nutrition Assessment Score Card' no less than 68.6 per cent of the children showed definite signs of malnutrition. It is the considered opinion that the majority of the other defects, particularly dental caries and anaemia, are due to indifferent feeding.

To date it has not been possible to arrange a scheme for the supply of milk and, if necessary, additional food, but this will be essential if improvement in the physical and mental condition of the child is to be effected. It is, however, fortunate that it has been possible to supply the children with multivitamin-cum-mineral tablets which have been very generously given by the American Friends Service Committee, but this is not the solution; the children must receive a well-balanced diet.

There has been a very gratifying response from the parents and the teachers, and undoubtedly they have realized the necessity for health education. This, in itself, has already shown a marked improvement, particularly in the attitude of the child towards life in general.

I wish to acknowledge my indebtedness to the Director, All-India Institute of Hygiene and Public Health, Calcutta, Dr. John B. Grant of the Rockefeller Foundation, and later Lieut.-Colonel C. K. Lakshmanan, for considerable assistance received in working out many of the details of the scheme. I am also indebted to our General Manager and to our Engineering Department for their ready help. To the parents and teachers of the school children I am thankful for their interest in the programme and their gratifying response.

Specimen forms received with this article are omitted to save space.—Editor, I.M.G.

A NOTE ON THE BIOLOGICAL ASSAY OF VITAMIN D IN FISH LIVER OILS

By G. KARMAKAR

and

M. N. RAO

(Section of Biochemistry, Nutrition and Physiological Hygiene, All-India Institute of Hygiene and Public Health, Calcutta)

Introduction

THE biological methods commonly employed for estimation of vitamin D are the 'line test' and the 'ash test'. In the former, the degree of calcification of bones produced in a rachitic rat by the test substance is taken as an index of its vitamin D content, i.e. a 'curative test'. In the latter, the potency of the test substance is taken as proportional to the degree of prevention of rickets in animals

on rachitic diet—a 'prophylactic test'. For both the tests, colonies of rats specifically reared up with low vitamin D reserves are recommended. But our experience in Calcutta showed difficulty in rearing up a large specific stock of young rats for the purpose under the tropical climate. The other alternative for us was to use a colony of rats on stock diet reared up in partial darkness. When these colonies of rats were being used it was often found that the degree of extreme rickets that is wanted in the curative or line test did not satisfactorily develop. Moreover, the values of the line test in the same group of experimental animals varied to a considerable extent. The values of the healing in the line test are liable to variation not only because of the biological material but also due to personal error in quantitative assessment of healing. We therefore wanted to try with the stock of available rats the efficacy of the

TABLE I

* With the fine needle dropper used, 160 drops of standard oil make 1 c.c. and is equivalent to 62 I.U. of vitamin D. 180 drops of shark liver oil make 1 c.c.

† The numbers indicate the degree of healing in a scale in which 0 indicates full rickets and 6 indicates maximum calcification.

alternative ash test in which the accurate percentage of ash is taken as the criterion instead of the healing values of line test wherein the personal error is likely to vitiate the results.

Experimental

The following rachitogenic diet used by us was a high calcium and low phosphorous diet :—

Rachitogenic diet

	Per cent
Yellow maize (powder) ..	60
Whole wheat ..	25
Gelatine ..	10
Calcium carbonate ..	4
Sodium chloride ..	1

Young rats weighing about 30 gm. were kept on the above diet for 4 weeks in complete darkness. During this preparatory period the rats were weighed twice a week and also the amount of food consumed daily was weighed to detect any loss of appetite which is supposed to lead to spontaneous healing of rickets. After making sure that all the animals developed complete rickets by doing a line test on some of them the rats were divided into five groups : three groups on graded doses of standard oil and the fourth and fifth groups on oil of unknown potency. The test period was for 10 days and the oil was given in 2 doses. The results are given in table I.

Values of average healing (column H) are plotted against the logarithm of the doses (column C) and a mean curve is drawn through them.

From this curve the abscissæ are found out corresponding to the average healing for the shark liver oil, and the values are calculated in table II.

TABLE II

Dose in drops	Average healing	Abscissæ	Antilog of the abscissæ (represents the vitamin D content)	Vitamin D (I.U./c.c.)
24	1.88	0.32	2.1	15.8
12	0.88	1.97	0.93	14.0

Starting with this oil of known potency an ash test was done on a group of 22 rats obtained partly from the laboratory stock and partly from the market. The rats were divided into four groups, two for feeding the standard oil and two for the shark liver oil and the doses were given from the beginning of the experiment. The doses selected were within the limit of prophylactic doses, i.e. one-fifth of the curative dose and even less and therefore one would expect partial calcification of the skeleton. The feeding was continued for about 7 weeks after which the animals were killed and the skeleton separated from the rats by the method of

Subrahinanyan, Duckworth and Godden (1939). The method consists in removing mechanically as much of the soft parts from the skeleton as possible and subsequently incubating the skeleton with papain to digest the remnants. By this method it was found that even the intervertebral ligaments are digested and the vertebræ are loose.

The short bones, the vertebræ, the small bones and the long bones of each of the animals are preserved separately for ashing to find any relative differences. The ashing to a constant weight is done after extracting the bones in alcohol and ether for 6 hours to remove the last traces of fat. The results of the analysis are given in table III.

TABLE III

Ash test

Total dose of vitamin D given during the whole experimental period	Average percentage ash (of the entire skeleton)
STANDARD OIL	
30 drops (11.6 I.U.) ..	59.06
60 drops (23.2 I.U.) ..	59.40
SHARK LIVER OIL	
60 drops (5 I.U. as found by line test)	59.09
120 drops (10 I.U. as found by line test)	59.26

Conclusions

Table III shows that irrespective of the graded doses of vitamin D the percentage ash is uniformly constant signifying that there has been spontaneous healing of rickets. Probably, the greater time that is taken for the ash test, i.e. nearly 8 to 10 weeks, was responsible for the spontaneous healing. But in the case of the line test the shorter time gives lesser chances of spontaneous healing. Hence the line test appears to be the test of choice whenever the specific stock colony of rats cannot be reared up for any reason. The line test is used as a routine in this laboratory.

The method of reporting the results with line test from this laboratory may be of interest. The values allotted to the degree of healing depend purely on personal judgment. To avoid this personal error the ends of the bones are all enlarged and photographed. This facilitates not only a permanent record but of check up by different workers. The specimen is mounted on a flat white surface and illuminated with two 50 watt Philips photographic lamps at such angles (about 45°) as to avoid

any dark shadows. The camera (Contax II with Sonnar 1.5 lens) is mounted on a universal stand and Zeiss micro-enlarger $\times 2$ used for magnification. A sample photograph is annexed (see plate X).

In this connection it may be mentioned that during our estimation of vitamin D content of different food samples by the line test we could not produce complete rickets on rats purchased from the market (weighing 25 to 30 gm.) when we kept them on the rachitogenic diet for even 6 weeks or more. This shows that unless the animals are bred in the laboratory on a restricted diet it is useless to attempt the line test method for the estimation of vitamin D. The ash test mentioned on the other hand is in our experience a failure in a hot climate although the animals are bred in the laboratory.

Summary

The rearing up of a specific stock colony for vitamin D assay in a tropical place like Calcutta is difficult. When the stock is not quite satisfactory ash test is not of much value. The line test is the test of choice.

Acknowledgment

The work was undertaken under the direction of Dr. G. Sankaran, Professor of Biochemistry, Nutrition and Physiological Hygiene. We sincerely thank him for his co-operation and guidance.

MALARIA AND IMMUNITY

(Reprinted from the *Indian Medical Gazette*, Vol. 32, April 1897, p. 141)

It is only press oneself in general terms the liability of any given person to any infectious disease. On all sides we see instances in which the apparently feeble escape, while those who seem best fitted to combat the inroads of disease are struck down. The question of individual immunity from disease, together with that of the powers of individual resistance, forms a most interesting study, and the theories at present arrived at, though not strictly conclusive on all points, are satisfactory to a certain extent and help us to solve some of the difficulties regarding personal antagonism to attacks on the part of disease germs.

So far we are of opinion that we may safely say that in all cases those who depart most, in whatever way, from the ideal standard of bodily health will be most likely to suffer from malarial infection, and that, in those who appear to be

in perfect health and yet suffer, the perfection is only apparent; there is something or other below par. The liability to contract malarial diseases is very marked among strangers visiting a malarious district for the first time, and this liability is often increased when such persons, ignorant of their danger or careless in the joy of health, do not take proper precautions to minimize the possibility of infection. They may be travellers, explorers, surveyors or soldiers who are living somewhat below their ordinary habit as regards food and dwelling accommodation. They are incurring unusual fatigue both of mind and body, and it is at such times that they will fall victims to malaria. The watch-dogs of the body share in the general weariness, and the enemy enters into possession. Conditions, such as excess in eating or drinking, long abstinence from food, dyspepsia, diarrhoea or 'chills' from wet clothing or wet feet will predispose the individual to attacks of malaria; as will also undue exposure to a hot sun. Certain races are said to be more or less immune and able to dwell in malarial regions with impunity. The negro resists malaria, and the aborigines of certain countries seem also to dwell in the midst of alarms in comparative safety. Writing of Nepal, Captain Eden Vansittart mentions certain tribes dwelling in most malarious spots in the Nepal terai, which apparently suffer little inconvenience from their malarial surroundings. Darwin accepted the undoubted differences, in constitution, in powers of acclimatization and in liability to certain diseases, among the various races of mankind. He says regarding the negro: 'They likewise escape to a large extent the fatal intermittent fevers that prevail along at least 2,600 miles of the shores of Africa, and which annually cause one-fifth of the white settlers to die and another fifth to return home invalided. With the negro the immunity, as far as it is the result of acclimatization, implies exposure during a prodigious length of time . . . and the Revd. H. B. Tristram states that there are districts in Northern Africa which the native inhabitants are compelled annually to leave, though the negroes can remain with safety'.

Individuals of a race thus immune may, however, lose their 'protection' by long residence in non-malarious countries, and we frequently find negro sailors in the port of Calcutta suffering from malarial fever. As for the Hindus and Mohammedans of Bengal there is, as a rule, no immunity, and they suffer quite as much as Europeans settled, or working, in the country. Some may, and apparently do, acquire a certain tolerance of malaria; but this tolerance, so far as we can see, never extends to protection from mild attacks or continuous deterioration of constitution. It may be that in many persons the tolerance is only a deadening of the system to the irritation produced in its tissues by the *plasmodium malariae*. The poison of malaria is not contagious; but there is some reason to

believe that the foetus *in utero* may be infected from the maternal blood should the parent suffer from *malarial fever* during pregnancy.

The inherited results of acclimatization in *malarial* areas through long ages may, therefore, give some power of resistance to the individual, and, conversely, those who have no such inheritance, will be the more liable to suffer from *malaria*. Even among the latter it is a matter of common knowledge that one person resists disease better than another, and we must seek some reason for this difference. Setting aside the question of prophylactic precautions, the value of which in diminishing our liability to disease is self-evident, have we anything within us which guards us against the attacks of bacteria, and protozoa such as the *amœba* of *malaria*? The liability to serious disease will no doubt vary with the amount of active poison imbibed, but with such quickly multiplying bodies as the *plasmodia*, a very small amount must suffice when the individual is in poor health. The studies of Metchnikoff have shown that there are certain leucocytes, often called 'phagocytes', whose duty seems to be that of seizing and destroying bacteria or other poisons entering the circulation through any of the *viæ naturales*. These phagocytes no doubt attack the *plasmodium malarie* in the lungs, œsophagus and intestinal canal, as well as in the circulation, and when in full vigour, or when dealing with only a small number of enemies, seem able to defeat them. These cells will naturally share in any illness or weariness of the body, and at such times man offers an easy prey to parasitic foes. The action of these leucocytes is treated at length in a work, by Gaston Chatenay, to which we refer the reader. It must be noted here, though well known, that the *plasmodia* of *malaria* do not form any *antitoxins* in the body, and their presence confers no promise of reduced liability in the future but rather the reverse. Herein they differ from most of the bacteria which seem to do us an unconscious kindness in producing substances and states of body which for a time protect us from further attacks of a like nature.

We cannot do better than close this article with a quotation from a lecture by Dr. G. Sims Woodhead. His remarks immediately concern protection from the attacks of tubercle bacilli, but apply with equal force to other diseases: 'It has now been very generally accepted that passing to and from the patches of lymphoid tissue in the walls of the alimentary canal, into and out of the canal itself, are numerous leucocytes, amœboid cells, or lymphoid corpuscles, as they are sometimes called. Further, it has been demonstrated that these small cells have the power of taking up foreign particles and of digesting them, or of so transforming them that unless they consist of particles of pigment they disappear; amongst these foreign bodies may be numbered bacteria of various kinds; so numerous, indeed, are bacteria in this position at certain periods of digestion that, by

the use of proper staining methods, they can be readily demonstrated lying in the bodies of the leucocytes, whilst these small cells, in turn, with their contained micro-organisms, may be seen lying embedded in the large epithelioid cells of the lymph tissue. These observations are so readily made out and have been so repeatedly confirmed, and the appearances presented are so very similar to those described by Metchnikoff as occurring in connection with the phagocytosis carried on by the leucocytes of the circulation, that very naturally the two processes have been compared and a phagocytic function has been assigned to the lymphocytes of the tonsils and to the cells of the adenoid tissue of the lower reaches of the intestinal canal'.

LONDON LETTER

(Reprinted from the *Indian Medical Gazette*, Vol. 32, April 1897, p. 145)

THE attitude of the people of India in the face of the drastic measures which the Government has been compelled to resort to in order to stay the spread of plague is wonderful. Never in the whole history of British rule in the East has the subject been subjected to such uncompromising interference with his liberty—with his personal movements, his domestic privacy, his prejudices and cherished traditional customs. Evacuation of dwellings, forcible cleansing or destruction of these, removal of the sick to isolation hospitals, inspection and detention of travellers—these and similar proceedings must to a sensitive, exclusive and conservative race be most unpalatable and irritating, and yet they seem to be submitted to without a murmur. Even the strongest religious feelings are lacerated, as by the prohibition of the Mecca pilgrimage, and the Mohammedans who are not prone to suppress their sectarian fervour, manifest no resentment. Further, the municipal institutions which were established for the purpose of educating communities in governing their own affairs, and which were intended to entrust a measure of political responsibility and power to the masses, have been somewhat roughly handled, and as in Calcutta and Bombay the Government has interfered to supersede their slow, halting and niggardly efforts by instituting agencies empowered to act more vigorously, thoroughly and liberally, and no loud voice of protest is raised to condemn the rude tyranny of the foreigner. The fact of the matter is that the crisis is a serious one, and Indian populations feel it to be so; and while the strong steps which Government has been compelled to take in order to save life and avert disaster, vital and commercial, are acquiesced in by the victims of the plague and its attendant panic, the propriety and necessity of them is fully and admiringly acknowledged by the rest of the civilized world. At the same time that a British Government is compelled to do things

NOT NERVOUS BUT 'NERVY'

Even in these days there is little evidence of nervousness, but overwork and strain make themselves felt however much their external manifestations be controlled.

Thus the overworked business man may suffer from headaches and insomnia, for the relief of which he needs a sedative that will increase his working capacity.

VEGANIN satisfies this need. It is composed of acetylsalicylic acid, phenacetin and codeine, each in small but sufficient dosage, and has a specific synergistic effect in disorders consequent on over-strain.

VEGANIN is neither toxic or habit-forming. It is not advertised to the public.

in India which are calculated to irritate and annoy Indians, a generous British public has contributed nearly half a million of money for the relief of the Indian famine which now appears to be in its acutest stage. I was present last night and took part in a discussion on Sanitation in India at the Parke's Museum under the auspices of the Sanitary Institute. It was opened by an interesting paper by Mr. Baldwin Latham, which, as might be expected, dwelt prominently on the importance of executing sanitary works for supply of water and sewage removal in cities and towns. The peculiar difficulties which existed in India with its high temperature and heavy rainfalls and dead levels, and the means necessary to overcome them were clearly and shrewdly dwelt on. The subsequent speakers diverged into a number of cognate matters, and the subjects of sanitary education, village sanitation, and utilization of excreta as manure were prominent among these. One speaker contended that the native Indian, though much has been said and written to the contrary, is not uncleanly in his instincts and ways according to his light, that in matters of personal and domestic cleanliness, he was scrupulously, elaborately, laboriously cleanly, in fact that the whole centre system was a protest and precaution against contamination. The instinct of cleanliness being there, it only required education to ensure its proper direction and application. This view seemed to commend itself to the meeting. As regards sanitary education, it was suggested that this ought to be an integral and essential element in the teaching and training of the young in schools. This is well as far as intellectual knowledge goes, but social education as regards the home, the village, the town, the city is also needful, and this cannot be imparted practically and usefully in schools. It is here that the active enlightened Government comes in to supplement and apply book-knowledge. Sanitary administration and sanitary work are the means to the end of social sanitary education. It is in this matter of concerted, associated action to sanitary objects that, as I recently pointed out, the social codes and social customs of the natives of India are deficient, and it is to the purpose of supplying this deficiency and creating salutary habits of common life, that the efforts of Indian administrations have been and must continue to be devoted.

There was a strong feeling in the meeting that the village life of India must not be too rudely disturbed, and that customs which are sanitariously harmless or even beneficial, such as the early morning resort to the field or bush, must not be interfered with even though they differ from those of western nations. The restoration to the soil for the useful purposes of material derived from the soil is a rational process, and, when carried out with proper precaution, a safe and profitable proceeding. But there are matters in rural India which do

demand intervention, and the condition of drinking and cooking water is assuredly the chief of these. On the question, Mr. Baldwin Latham was very strong, and he detailed with satisfaction many illustrations of the benefit of health which had followed arrangements for the supply of such water to Indian communities. The subject of several diseases in the European Army of India is being taken up with vigour. There are to be debates in both Houses of Parliament at an early date on the question. Lord Onslow's Committee has, I believe, completed its inquiries and is busy preparing its report. The Army Sanitary Commission has delivered a strong pronouncement in favour of active preventive effort; an influential meeting was held recently at the United Service Institution where the subject was warmly discussed for three hours, and as a result a committee has been organized of persons interested in the question to promote the adoption of measures calculated to reduce the amount of suffering and disability caused by these maladies in the army. What the outcome of all this agitation will be it is difficult to predict. These diseases were somewhat arbitrarily removed from the list of contagious affections for whose prevention regulations could be framed in India under the laws, and it is probable that they may be restored to the list, and means of detection and segregation, combined with medical and moral treatment, resorted to. The extent to which constitutional infirmity is caused in civil life among the rising generation by the marriage of syphilitic soldiers after their discharge from the army is clearly occasioning alarm.

In Russia there was a commission not long ago which sat for the purpose of investigating the extent to which syphilitic disease was sapping and degrading the national health. Very stringent and searching ordinances were recommended, with a view to the detection of disease in both men and women in civil as well as in military life, and the detention in hospital of persons dangerous to the common welfare until they ceased to be so. It is on this principle that other communicable maladies are recognized and treated, and although the circumstances are in the case in question peculiar and difficult, the policy of blind inaction appears to be getting discredited in this country.

Current Topics, Etc.

Son or Daughter ? *

By K. A. SHAH, M.B., B.S.

Ranchhodlal Dispensary, Ahmedabad

Of all the peoples in the world, perhaps the Hindus alone believe that a son saves them from hell.

* A paper read before the Ahmedabad Medical Society on 21st December, 1946.

Nevertheless, mankind has, down the ages, always desired a male issue. If the Kings want heirs to their thrones, the aborigines want warriors to fight their battles and workers to till their land. No wonder then that speculation has been rife and fertile as to what determines the sex of the foetus *in utero*, and as to whether anything can be done to influence it.

According to the *Encyclopedia Britannica* (9th Edition), there were hundreds of theories current in the 17th and 18th centuries. Some of these had to do with the quality or quantity of food, some with elevation of abode, some with conditions of temperature and some with the age of parents, their mode of life, habits, rank, etc. For example, overfeeding the mother was thought to result in a girl, underfeeding in a boy. The older parent was supposed to impress its own sex upon the offspring by some, while others held that the younger parent, in cases where there was a marked disparity in ages, induced its own sex in the offspring. It is believed in Southern France and Italy that the wearing of a hat at the time of intercourse is a means to begetting a son, while in Poland the wearing of Sunday clothes on this occasion is held to have a powerful influence. In other places faith is placed in the wearing of boots at mating time (Sandell, 1937).

A belief which has remained unshaken for many centuries is that if the woman has been sufficiently roused to a complete orgasm at the time of intercourse the result will be a male child (Sandell, 1937). It appears that this was perhaps the secret of the successful prediction which Louis-Philippe, King of France (in the nineteenth century), could make about the sex of his unborn children. When asked how he could do so, he replied, 'When I wish a girl, I offer her to the Queen; when I wish a boy, I expect that she offers him to me.' Shakespeare (Erskine, 1925) wrote, 'A man who goes to bed drunk begets a daughter'. Albertus Magnus, in the 13th century, advised, 'Lie on the right for a boy, on the left for a girl'. The theory that the male parent had no influence on the sex of the embryo was announced by Rumley Dawson about 40 years ago. Erskine (1925) informs us that in France brides are seriously advised to sleep on the right side if they desire sons (quoting in support *Lancet* of 1870). Behind these precepts is the belief that the right ovary produces male ova only, and the left, female ova. Blakely knew of a patient who had twins, a boy and a girl, after unilateral oophorectomy (quoted by Clifford White, in the *Medical Annual*, 1939, p. 395). In her book written in 1929, Erskine states, 'The theory that the sex of a child is fixed before the ovum is fertilized has now become an absolute certainty as a result of thousands of successful tests which have established it. The male according to science is not a sex-determining begetter: he is simply and only a fertilizing agent.' As we shall see, the truth is the other way about.

According to Dhanvantari, *Shukra Bāhulyāt Pūmān, Ārtava Bāhulyāt Stree*, a son is born when there is excess of semen; a daughter, when the vaginal secretion is in excess. This almost anticipates Unterberger's theory. The *Pāraskar Grihyasūtra* recommends that one desirous of a son should go to his wife daily: *Putrakāmo Abhigacchhet Nityam*. A more definite instruction is *Putrārthee Yugmadine Kanyārthee Ayugmadine* to have intercourse on even days for a son, and odd days for a daughter; and the time recommended as most fruitful (which is in conformity with modern scientific conceptions) is first sixteen days [counting from the beginning of menstruation].

The sex of the foetus, as we know to-day, is determined at the time of conception; and the determining factor is the spermatozoon and not the ovum. Like all hereditary characters, sex is also determined by chromosomes. Pathak believes that the ancients had this knowledge about chromosomes and cites the following from Charak: *Yasya Yasya Avayavasya Beeje, Beejabhāga Upatāpto Bhavati, Tasya Tasya Avayavasya Vikrutir Upajāyate*. In my opinion,

Pathak is mistaken. What is here meant is something akin to Darwin's 'Gemmules'.

In 1891 Henking had observed that in the spermatogenesis of a bug, the sperms are of two kinds distinguished by the presence or absence of a certain chromatin element. In 1899 McClung identified the differential element as a chromosome. It was then established that there are two classes of sperms in equal numbers with one chromosome—the X-chromosome—as a differential. McClung (1925) advanced the theory that this chromosome determines sex. A startling theory such as McClung's did not have to wait long before being tested. Cytologists began to turn their microscope on the cells of the male and female of various species. In most species the females have an even number of chromosomes, including two X-chromosomes, whereas the males have only one X-chromosome in some species and in others (including man) the single X-chromosome is accompanied by a smaller chromosome, the Y-chromosome. In 1918, Painter showed that the unreduced or duplex number of chromosomes in the testis of Europeans and Negroes is 24 pairs of which one pair is unequally mated (the unequal pair being XY). Consequently when reduction occurs the chromosomes separate out in two sets, 23 autosomes + X and 23 autosomes + Y. Thus two sets of spermatozoa are formed—half carrying the X-chromosome and half carrying the Y-chromosome. Later, Evans and Swezy (1928) confirmed Painter's work on the male and demonstrated that the female of the human species has an equally matched XX pair (Hogben, 1931). All the ova therefore carry one X-chromosome.

We have seen that the sperms contain X and Y chromosomes in equal numbers. Sperms with X when they combine with an ovum give females (XX), while those with Y give male offsprings (XY). Observations in the fruit fly have shown that it is the lack of one X that gives rise to a male; the Y-chromosome is not necessary to produce a male.

Is it possible, once the conception has taken place, to forecast the sex of the child? It was suggested 80 years ago that before labour a foetal heart rate of 124 or less indicated a boy, whereas that of 144 or more a girl. It is difficult to believe that there exists a difference of this kind when throughout the whole life the sexes do not show such a difference. In any circumstances comparatively few foetal hearts are below 124 or above 144 before labour commences (Blakely, S. B., quoted by Clifford White in *Medical Annual*, 1939, p. 395). In 1934 Davis of Boston injected testicular extract into the skin of pregnant women and noted the reaction of the skin in four to ten minutes. Entire absence of reaction indicated a female, and a marked positive reaction, characterized by temporary local redness, a male. Davis' results showed 85 per cent accuracy in 534 cases examined. I have not come across any confirmation of this report.

Male sex hormone (androgen) can be extracted during pregnancy and it is thought that the amount excreted has some relationship to the sex of the foetus. Thus, according to Goecke, in instances in which the foetus is male, androgenic substances are found in the urine in 80 per cent of the cases (1 comb unit in 3 litres of urine). On the other hand, in case of a female foetus, no hormone is excreted since, according to this author, it is apparently stored, unused in the placenta (Wolf, 1939).

According to the Egyptians (about 3,500 years ago), 'To tell if a woman is pregnant or not pregnant barley and wheat are moistened with a woman's urine daily like dates or pastry in two bags. If they either germinate, so will she give birth; if the barley germinates, so will it be a boy; if the wheat germinates, so will it be a girl; if they do not germinate, then she is not pregnant'.

A German scientist set out to test this theory. His observations on a hundred women enabled him to make a correct diagnosis of the sex of the embryo in eighty women. Two American workers who repeated their experiments on a large scale in 1935 were, however,

unable to corroborate this, and came to the conclusion that the method is unreliable.

Writers on Ayurveda also describe certain signs by which the sex of the foetus can be discerned: 'If the right eye of the pregnant woman is heavy, if the right breast secretes milk earlier, if the right thigh is more full and her face lustrous, if she yearns after and dreams of objects of the male gender, or dreams of flowers like the lotus or fruits like the mango, her baby is likely to be a boy'. The contrary signs indicate a girl.

According to popular beliefs the pregnant mother of a boy has a more prominent front than behind: eats less and yet is more active and has a lustre on her face. The pregnant mother of a girl, on the other hand, has a figure more prominent at the back, eats more and yet is apathetic: she yawns frequently and has a dull look.

Is it possible in some way to so influence the male (i.e. the Y-bearing) sperms that they will win the race in reaching the ovum in the uterus?

According to the ancients, so long as the embryo remains undifferentiated (say, in the first two months), attempts should be made to turn it into a male. This process or ceremony is called *Punsavan*. It is one of the twelve (or sixteen) *Samskaras* or sacraments of Hindu life. Over and above the performance of religious ceremonies, it is recommended that the juice of certain plants, e.g. *Solanum xanthocarpum* (*Laxmana*), *Sida cordifolia* (*Sahadeva*), or the young buds of the banyan (*Vatashunga*) tree, be dropped into the right nostril (for a girl, in the left). Vagbhata writes that strong and vigorous human effort can sometimes overcome Destiny and recommends that a small male figure made of gold or silver or iron be put in some milk and that milk be given to the pregnant mother.

This figure should be made red hot in the fire and then put in milk. The time should preferably be when the moon is in the *Pushya Nakshatra*. Arundatta, a commentator of Vagbhata writes, however, that if the foetus has already been of the female sex, no human effort can convert it into a male, and the process of *Punsavan* is useless.

About a year ago in the *Journal of the Indian Medical Association*, Dr. P. C. Bose wrote that, at the gynaecologists' conference at Amsterdam in 1938, 'Many speakers reported remarkable results of widely divergent methods in voluntary determination of the sex. Billman treated 31 cases according to Unterberger's method which relies on the theory that the sex of child is fixed at conception and depends on the chemical reaction of the interior of the vagina, alkalizing which causes the development of the male child.'

Unterberger treated sterility in cows by douching with bicarbonate of soda and obtained very successful results. He then applied the method to sterile women and found that in the successful cases the children born were invariably boys. He went a step farther and applied the method to 74 women who hitherto had given birth exclusively to two, three or four girls each. He treated the vagina by alkaline douching before intercourse took place, and success again followed; a series (number not stated) of boys were born. Paul Weill of Strasbourg treated 150 women for sterility by rendering the vagina alkaline. Half of these women, that is 75, conceived as a result of this treatment and the child was a boy in every case. He also treated a number of women who hitherto had given birth to two to three girls each. In all these cases boys resulted. I must admit these are impressive figures. But equally impressive, if not more, were the figures presented by Schöner at the Third Sexual Reform Congress held in London in 1929. He set out to establish that the right ovary produces more boys than girls, and the left more girls than boys, and both in the same proportion (2 : 1). He arrived at the conclusion ('unambiguous') that 'it is not the sperm but the ovum which determines the sex', and that 'the extra chromosome is not responsible for the determination of sex' (Wolf, 1939). We know to-day that he was wrong.

McPhee and Eaton of the Bureau of Animal Industry of the U.S. Department of Agriculture carried out an extensive investigation 'to determine whether the sex ratio can be altered significantly either by douching the female with acid and alkaline solutions or by changing the pH of semen used for artificial insemination'.

Experiments were conducted on rabbits and swine. In all, 2,383 rabbits and 219 swine were born. The results failed to show any significant modification of the normal sex ratio for the species as a result of the acid and alkali treatments (McPhee and Eaton, 1942).

In the Department of Genetics of Wisconsin University, Casida and Murphree carried out a similar experiment *in vitro*. They treated rabbit sperm with solutions of sodium bicarbonate and lactic acid and used these sperms for artificial insemination. No significant disturbance of sex ratio of the offspring was produced by either of these treatments. 'Additional trials with sodium bicarbonate in which tests were made of its effect upon the speed of travel and upon the survival of the male and female determining sperm failed to show any differential effect' (Casida and Murphree, 1942).

Quisenberry declares, '... douching of farm animals to modify the sex ratio seems not only a hopeless procedure, but a dangerous one as well' (Quisenberry, 1945). His results are worth quoting. By using the lactic acid douche, which is supposed to give female offspring mainly, if not solely, 51.6 per cent males were born; whereas the use of sodium bicarbonate which is supposed to facilitate male births gave rise to 54.5 per cent of males only!

There is at least some difference between the Y-bearing and the X-bearing sperms. The Y-bearing sperms have smaller heads (by 1/1,000th of a mm.) and it was suggested by Huxley that the two types be separated by some such process as centrifuging, and the sperms used for artificial insemination to ensure the birth of the desired child. So far as I know, this ingenious suggestion has not been taken up. Another difference between the Y-bearing and X-bearing sperms is that the former are somehow or other able to reach the ovum much more quickly than their fellows. It is recorded that many more males are conceived than females. Scheinfeld and Schweitzer (1939) report that in early abortion (about 3 months), the males outnumber the females almost four to one. In the fourth month, aborted males are double those of females, in the fifth month 145 males to 100 females, in the next four months the proportion drops further, but just before birth there is a rise to almost 140 males aborted (or still born) to every 100 females. Even at birth the preponderance of males over females continues; there are 105 males born to 100 females. Similar figures for our own city, in 1945-46, are 107.2 males for every 100 females.

Sulphaguanidine in the Treatment of Cholera Under Rural Field Conditions

(From a paper by Dr. S. C. Seal read at the Indian Science Congress, 1947)

RECORDS of the trials of sulphaguanidine in the treatment of cholera are all based on studies of cholera cases admitted into hospitals where the patients are generally brought in in an advanced stage of the disease and treatment is carried out under controlled conditions. The effect of the drug when applied under actual field conditions in which both the community and the environment remain uncontrolled was considered worth studying. Opportunities were available for such trials in several small outbreaks of cholera occurring within the Singur Health Centre Area in the district of Hooghly, Bengal. The drug was supplied by the Director, School of Tropical Medicine, Calcutta, and the actual work was carried out by Dr. S. C. Seal, M.B., D.P.H., Assistant Professor of Epidemiology, All-India Institute of Hygiene and Public Health, Calcutta, with the help of Mr. Purnendu Chatterji, Field Supervisor, Gastro-Intestinal Disorders Inquiry under the Rockefeller Foundation. We have received Dr. Seal's report on this work.

Thirty small outbreaks of cholera involving 29 villages were investigated during the period between middle of August 1944 and middle of September 1945. There were altogether 290 cases affecting all age groups, females preponderating over males. The gross fatality rate was 24.5 per cent, both sexes contributing almost equally. One hundred and thirty-four cases were treated with sulphaguanidine (group A) with only 2 deaths and 154 cases by other methods (group B) with 67 deaths. The fatality rate is thus 1.5 and 43.5 per cent respectively. The difference is obviously highly significant. The mortality rates among the moderate and severe cases were respectively 1.9 and 2.6 per cent in group A against 18.5 and 70.2 per cent in group B. The statistical analysis of the data in relation to the various factors which influence the results of treatment indicate a definite superiority of sulphaguanidine over other treatments.

The dosage used for a clinical cholera case (adult) was generally as follows: Initial dose—3 grammes followed by 3 or 2 grammes every 3 or 4 hours (repeated immediately if vomited out) till the number of stools is reduced to 2 or less per day, then one gramme every 6 hours for the next 24 hours. The drug is better used in powder form. The total average dose varied with age, severity and time of commencement of treatment. The highest total dose in mild cases was 14 grammes, in moderately severe cases 25 grammes and in severe cases 28 grammes, the gross average being about 10 grammes exclusive of supplementary measures. No complications or toxic symptoms developed in cases treated with this drug.

A Simple Method for Performing a Wassermann Test on Anticomplementary Serum

By ALBERT TARAN, B.A.

(Abstracted from the *Journal of Laboratory and Clinical Medicine*, Vol. 31, No. 9, September 1946, p. 1037)

A SIMPLE procedure has been given which permits the performance of a Wassermann test on anticomplementary

mentary serum and which eliminates the necessity of taking further specimens of blood from the patient.

The procedure is based on the saturation of the serum with undiluted complement to satisfy the 'fixing' properties of the serum. To 2 c.c. of anticomplementary serum is added 0.3 c.c. of undiluted complement and placed in 37°C. water bath for thirty minutes and in 56°C. water bath for thirty minutes to destroy excess complement. The Wassermann test is performed in the usual manner.

In all cases complete hemolysis was present in the control tube, and the tests were reported as negative, doubtful, and positive.

Known negative and positive sera were treated in the same manner as the anticomplementary sera in order to check on the effects of complement saturation. The results of these tests were the same with and without complement saturation.

There were excellent correlations between the Wassermann test on anticomplementary serum and the repeated Wassermann test on fresh serum and the Kahn test.

Present Status of Diasone in the Treatment of Leprosy: Brief Clinical Note

By G. H. FAGET

R. C. POGGE

and

F. A. JOHANSEN

(Abstracted from the *Public Health Reports*, Vol. 61, No. 26, 28th June, 1946, p. 960)

FAGET and co-workers at the National Leprosarium, Carville, La., summarize the results in 104 patients of leprosy treated during the past 2½ years with diasone which is a derivative of diamino-diphenyl-sulphone. In all cases the drug has been used by mouth in daily doses varying for adults from 0.33 gramme to 1 gramme and for children from 0.17 gramme to 0.5 gramme.

In about 30 per cent cases the treatment had to be discontinued because of toxic reactions or other causes, in about 7 per cent the treatment has been carried only for less than 6 months, and in the remaining 63 per cent cases (66 cases) the treatment has been carried for 6 months or longer. Of these 66 cases there is objective improvement in specific leprosy lesions in 65 per cent of the patients; in another 12 per cent the improvement is limited to changes in various non-specific infections which appear to benefit from diasone therapy; in the remaining 23 per cent the improvement is largely subjective and no demonstrable change is claimed; there are no cases that are clinically worse. The authors conclude that diasone is suitable for oral administration and that patients with leprosy usually improve clinically within the first six months of treatment on a dose of 1 gramme daily for the adult.

Promizole Treatment of Leprosy: A Preliminary Report

By G. H. FAGET

R. C. POGGE

and

F. A. JOHANSEN

(Abstracted from the *Public Health Reports*, Vol. 61, No. 26, 28th June, 1946, p. 957)

FAGET and co-workers at the National Leprosarium, Carville, La., have presented a preliminary report on the treatment of leprosy with promizole which

is a derivative of diamino-diphenyl sulphone-diamino-5-thiasoliphenyl sulphone. Promizole is less toxic than promin which is another derivative of diamino-diphenyl sulphone, reported on favourably in the treatment of leprosy. The present report is a preliminary report based on 7 cases treated for a period of at least 1 year. Originally, treatment was started in 11 cases; in 4 it had to be discontinued, in two patients because of the toxic reactions, and in another 2 for other reasons. The treatment was started with a dose of 0.5 gramme given three times daily, the dose was gradually increased to 2 grammes given three times daily over a period of several weeks. All the 7 patients have tolerated the drug well in doses up to 6 grammes daily. At the end improvement has been seen in all the 7 cases. The authors conclude that promizole is well tolerated by patients with leprosy and that clinical improvement occasionally can be demonstrated more quickly with promizole than with similar sulphones such as promin and diasone. The authors feel that the therapeutic results so far obtained with promizole are sufficiently encouraging to warrant further clinical study.

Highlights of the Conference in Tropical Dermatology for American Doctors held at Mexico City from 6th to 18th August, 1945

By H. HARRIS PERLMAN, M.D.

and

MARQUIS R. HUFFMAN, M.D.

(Abstracted from the *Urologic and Cutaneous Review*, April 1946, p. 219)

THE 8th, 9th and 10th sessions of this Conference held on the 13th, 14th and 15th August, 1945, were devoted to deliberations on leprosy. These consisted of discussions and demonstrations. The discussions included general information on aetiology, treatment, control, geographical distribution, etc., of the disease; the classification of leprosy came in for special consideration. The defects of the classification adopted at the Cairo International Congress, 1938, were pointed out and it was stated that the best classification so far available was the classification by the Brazilian workers which divided cases of leprosy into three types: lepromatous, tuberculoid and non-characteristic. These three types were described and illustrated by cases. The demonstrations included demonstration of ocular complications of leprosy. In the conjunctiva the leprosy changes are most marked at the corneal conjunctival margin, i.e. the limbus. Keratitis is a frequent occurrence in the lepromatous type, and three types have been described: (1) Punctate keratitis, clearly observable by the corneal microscopes. (2) parenchymatous keratitis, which is the commonest type and which exists as a diffused infiltration of the entire parenchyma, and (3) true lepromatous resulting in the destruction of cornea. The iris and ciliary body are affected by a serious type of irido-cyclitis; an exudate forms which gives rise to synechia between the pupil and the lens.

Fatal Anaphylactic Shock

By JACOB WERNE

and

IRENE GARROW

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 29th June, 1946, p. 730)

ON 19th June, 1945, the death of identical twins after a second injection of diphtheria toxoid and

pertussis antigen, alum precipitated, was reported for investigation.

History.—D. M. and G. M., boys, aged 10 months, were brought to St. John's Long Island City Hospital (service of Dr. James M. Dobbins) on 19th June, 1945, at 7-15 a.m. D. M. was pronounced dead on arrival; the condition of G. M. was described as critical. He was cyanotic and dyspnoeic; respirations were shallow, rapid and laboured. Oxygen was given by mask, suction was applied for aspiration of mucus; 4 c.c. of nikethamide were given at 8 a.m., 3 minims (0.18 c.c.) of epinephrine at 8-15 and 2 c.c. of caffeine with sodium benzoate at 8-45. At this time the temperature was 99°F. Cyanosis continued to be present at intervals. One c.c. of picrotoxin was given at 9-30; respirations were then noted as being 38. At 10 and 10-30 3 more minims of epinephrine were given, and at 10-45 infusion of plasma was begun. Before 40 c.c. were given the subject was pronounced dead.

The family physician stated that nothing untoward was noticed immediately after the injections except that 1 twin bled slightly from the site, necessitating the application of an additional cotton pledget. The parents stated that following the first injection one month before (from another ampoule of the same product) D. M. vomited, had a temperature of 101°F. and cried considerably. One-half grain (0.032 gm.) of acetylsalicylic acid was given and by evening he was apparently well. G. M. remained symptom-free after the first injection.

After the second immunizing injections, both infants cried considerably on reaching home; they vomited and consumed excessive amounts of water, each taking about two full bottles. They then 'fell asleep' and when next noticed by their parents appeared 'lifeless'. Their position in the cribs remained unchanged, and they could be aroused only by loud noises. D. M. had a 'staring' expression; his temperature was 90°F. At 11-30 p.m., when his diaper was changed, he was found to be 'icy cold' and wringing wet with 'perspiration'. The parents explained that they regarded these symptoms as expected effects of the injections and therefore did not summon medical aid until 5-30 a.m., when D. M. appeared to be dead and G. M. gravely ill.

The twins were born at eight months' gestation, D. M. weighing 2 pounds 8 ounces (1,134 gm.) and G. M. 5 pounds 4 ounces (2,381 gm.). The former was placed in an incubator and developed normally. Both continued in good health. At 6 months they were vaccinated against smallpox.

The mother had been inoculated against diphtheria as a child but did not receive any injections during pregnancy. There was no history of allergy on her side of the family. The father described a sudden swelling of the lower lip while in the army, which disappeared as precipitously as it came on. After receiving his medical discharge he experienced another similar episode, which was diagnosed as 'allergic' by a medical officer who happened to be present at the time.

Post-mortem study.—At autopsy both twins were well nourished and well developed. The sites of recent inoculation in the deltoid region were marked by minute puncture wounds of the skin and a small amount of hæmorrhage in the underlying fat. There was no gross evidence of significant inflammatory reaction. The brain in each case felt softer than usual. The subarachnoid space contained excess fluid. The meninges, mastoids, middle ears and tonsils showed no evidence of infection. There was no regurgitation or aspiration of stomach contents. The thymus of D. M. weighed 28.4 gm. and showed numerous petechiæ; that of G. M. weighed 34.1 gm. The adrenals of D. M. weighed 3.0 gm. and those of G. M. 3.2 gm.; they showed no gross abnormalities. The heart contained both clotted and fluid blood in each instance. There were epicardial and pleural petechiæ. The lungs were salmon pink and air containing for the most part. In G. M. the parenchyma on section showed oedema; in D. M. there were conspicuous focal hæmorrhages in the dependent portions. The mucosa of the larynx, trachea and bronchi was pale and free of exudate. The

broncho-pulmonary lymph nodes were not enlarged. The liver of D. M. weighed 350 gm., that of G. M. 370 gm. In D. M. it showed extreme congestion. The spleen and kidneys were moderately congested. The gastro-intestinal tract showed no gross lesions. The lymphatic follicles were normally conspicuous, as were the mesenteric nodes. The pancreas, biliary passages and genital organs were natural. There were no skeletal abnormalities. Post-mortem lung cultures were made and found sterile in each instance, and in addition a sterile post-mortem culture was obtained from the spleen of D. M.

Post-mortem serum was tested on four members of the laboratory staff for the presence of reagin after the prior intracutaneous injection of the biologic product with negative results.

The contents of the vial used in immunizing the twins, and of the vials bearing the same lot number submitted by the manufacturer, were examined by Dr. Jules Freund of the Bureau of Laboratories, Department of Health, City of New York, and the following results were obtained: 'The vaccine was found to be sterile; that is, the sterility test required by the National Institute of Health for biological products was satisfactory. The microscopic picture showed formed elements of the size and shape and staining qualities of Bordet-Gengou bacilli. Tests carried out on the skin of rabbits showed that there was no free diphtheria toxin in the vaccine. The identity test showed that the vaccine contained diphtheria toxoid, that is, combined with the diphtheria antitoxin, 0.5 c.c. amounts of the vaccine injected into the peritoneal cavities of white mice did not cause obvious toxic reactions. (The latter test is routinely done on biologicals for harmlessness.)'

The histopathologic study disclosed lesions consistent with death in anaphylactic shock. The skin at the site of inoculation (studied in G. M.) showed swelling and acute degeneration of collagen, arteriolar degenerative changes, thrombosis and hæmorrhage. Bacterial stains showed numerous forms resembling *Heinophilus pertussis*. The follicles of the spleen, lymph nodes and gastro-intestinal tract showed conspicuous macrophages containing abundant nuclear particles and cytoplasmic debris. There were numerous eosinophils in the lymphatic tissues. The thymus showed foci of hæmorrhage and necrosis, and extremely constricted arteries whose walls showed œdema, eosinophilia and endothelial swelling and proliferation.

The brain showed capillovenous engorgement, perivascular hæmorrhages, arteriolar narrowing and diffuse degenerative changes of some arterial walls, with cellular infiltration of the vessels and the surrounding space; this was mainly mononuclear, with occasional polymorphonuclears and eosinophils. Many nerve cells showed acute degenerative changes.

Heart sections showed focal necrosis of muscle, more accentuated beneath the epicardium and endocardium. Constricted lumens, œdema and necrosis of some arterial walls were observed, as were swelling and some proliferation of the endothelium. Perivascular hæmorrhages were frequent in relation to such areas. Sections of aortic and mitral cusps showed endothelial swelling and increased mononuclear cells throughout the leaflets.

The respiratory epithelium showed excellent preservation with intact cilia. (Fulminating respiratory infection, the most common cause of unexpected death during infancy, was thereby excluded.) Extreme narrowing of some bronchial and many arterial and arteriolar lumens was conspicuous. Mononuclear, slight polynuclear and slight eosinophilic infiltration occurred in both bronchial and pulmonary arterial walls. The pulmonary veins and alveolar septal capillaries were deeply engorged. The lymphatics were dilated with abundant protein precipitate. There were foci of pulmonary œdema, both interstitial and intra-alveolar, and foci of hæmorrhage and early intra-alveolar exudate, mainly polymorphonuclear, especially in the case of D. M. Fibrinous exudate and bacteria were not seen.

The liver sections showed extensive parenchymatous degeneration, most evident in the central two-thirds of the lobule: this took the form of granular and hydropic change, with pyknosis of nuclei and chromatolysis. The sinusoids contained abundant leukocytes, with a moderate number of eosinophils. Occasional focal necrosis was seen, mononuclears filling the parenchymatous defect; some multinucleated hepatic cells occurred in peripheral portions of some lobules.

The widespread visceral lesions encountered seem adequate to explain the profound shock observed clinically. The histological appearances point to acute vascular injury as the underlying cause. This results from the basic physiological disturbances that seem adequate to explain the apparently diverse manifestations of the anaphylactic state: contraction of smooth muscle and increased capillary permeability. The former, if severe enough in bronchiolar or pulmonary arteriolar muscle, is believed to cause death by asphyxia or dilatation of the right ventricle, as in the guinea-pig and the rabbit respectively.

In view of the high mortality that accompanies both diphtheria and pertussis during infancy, it is hoped that the publication of a report of these two fatalities will not deter the profession from continuing to practise immunization. It will be recalled that the family history was positive for allergy; the father suffered from what appeared to be episodes of angioneurotic œdema. It would seem that the influences of heredity and twinning deserve weight as determinants of individual predisposition in the cases reported here. A search of the literature disclosed no other fatalities following inoculation with pertussis antigen and diphtheria toxoid, whether separately or combined.

Delayed Serum Sickness Reaction to Penicillin

By EVERETT J. GORDON

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 29th June, 1946, p. 727)

THREE cases of delayed reaction to penicillin are reported. The first case was originally reported in April 1945, in the *Medical Bulletin of the Mediterranean Theatre of Operations* (restricted), but because of the limited distribution and availability of this publication it is again presented here in abstract form.

Case 1.—A white soldier, aged 23, was admitted to the evacuation hospital on 1st February, 1945, with pneumonia of the left hilar area. His treatment included a course of penicillin of 25,000 units administered intramuscularly every three hours for five days, a total of 1 million units. On the third day of treatment his temperature fell to normal, and his symptoms cleared rapidly with a fairly smooth convalescence.

Five days after the cessation of penicillin therapy he complained of the sudden onset of itching 'hives' on his arms and legs, soon spreading to his trunk. Investigation revealed no unusual contact such as clothes or soap and no deviation from the ward diet. The family and personal history was negative for allergy. All medication had been suspended two days before the onset of symptoms.

The following morning the urticaria had spread to involve the face, the entire trunk and all four extremities, despite treatment with ephedrine sulfate, intravenous injections of calcium gluconate and epinephrine in tablet (hypodermic) form. On the second day of the reaction the patient complained of swelling and persistent, aching pain in the phalangeal and metacarpophalangeal joints of both hands and in the joints of both ankles. Examination revealed a pitting type of œdema, local warmth, tenderness and painful motion of the affected joints; the pulse rate and temperature were slightly elevated.

Treatment hypodermically with epinephrine hydrochloride 1:1,000 solution was followed by a sharp decrease in the generalized pruritus and mild blanching of the erythematous areas, but the relief was only

transitory. In administering this drug it was noted at the time that there was little relief or disturbance from the use of the tablet form of epinephrine which apparently had deteriorated, whereas injection of the epinephrine hydrochloride solution not only relieved the symptoms of the reaction but also caused appreciable preordial distress and increased nervousness, including hand tremors. Substitution of epinephrine hydrochloride in peanut oil gave much more satisfactory and prolonged relief.

Urticaria persisted for three days, but the swelling and soreness of the hands and ankles did not disappear until the seventh day of the reaction: on this day an exfoliative type of dermatitis appeared on the palms of both hands, lasting three additional days.

Case 2.—A white soldier, aged 23, was admitted to this hospital as an overseas evacuee from the European theatre for further treatment of a compound fracture of the right elbow sustained when the bomber in which he was flying was struck on 2nd April, 1945, by fragmentation bombs accidentally released by an American plane overhead. After initial treatment overseas in which he received 2 million units of penicillin he was evacuated to the United States for further care. A resection of the right elbow joint was performed on 23rd October, 1945, under gas-ether-oxygen anaesthesia, following which penicillin was administered, a routine measure after surgery on previously compound fractures. He received 25,000 units every three hours intramuscularly for nine days, during which time his temperature and pulse remained within normal limits.

Two days after the cessation of this course of penicillin, while at home on week-end pass, he noted a small patch of hives, first on the left arm but soon followed by extension to the other arm and to the trunk, face and back. Within a few hours he noted pains in the joints in both hands and both feet. The following day there was fleeting pain in both knees, not severe; the pain in the left hand had subsided somewhat. He returned to the hospital, at which time examination revealed generalized urticaria and decided swelling of the fingers of the right hand, including the metacarpophalangeal joints; there was also swelling of the toes and metatarsophalangeal joints of both feet, more pronounced on the right.

Symptoms persisted for three days in an intense form despite the use of epinephrine hydrochloride; during this time there was pronounced oedema with almost complete closure of both eyes. The oedema of the right foot persisted for several days after other symptoms had subsided; a similar condition persisted in the right hand, but the recent surgical intervention in the right elbow clouded the mechanism of its production. Five days after the onset of the reaction all swelling of the toes and fingers had entirely cleared and the urticaria had not reappeared; however, an exfoliative dermatitis of both palms had appeared on the third day, and this was still present along with a mild, generalized pruritus. No signs or symptoms were present by the eighth day of the reaction.

On questioning, the patient gave no history of asthma, hay fever or other allergies, either in himself or in his family. The only other course of penicillin he had received was that given immediately after his injury.

Case 3.—A girl, aged 20, a member of the Women's Army Corps, was readmitted to the hospital in the dermatologic service with severe generalized urticaria which involved all the extremities and the trunk but not the face and was of obscure aetiology. She stated that she had been discharged from the hospital seven days before, after having been hospitalized ten days for acute follicular tonsillitis. During her previous hospitalization she had received a course of penicillin therapy of 25,000 units every three hours, administered intramuscularly, for a total of 1,600,000 units.

While at home seven days after the last injection of penicillin she first noted a severe urticaria of her trunk, rapidly followed by extension to all four extremities. It increased in severity despite the use of ephedrine sulfate. The following day she noted aching pain in

both knees and ankles, accompanied by mild swelling. She returned to the hospital, where a careful search for possible allergic sensitivities was made, including multiple scratch and intradermal tests. The history of recent penicillin therapy was disregarded.

The urticaria cleared three days after its onset, but the pains in the joints persisted in a mild form for an additional week. Seven days after the onset an exfoliative dermatitis of the palms of both hands appeared, and this persisted one week. Ten days after the onset the reaction had subsided except for the slight persistence of mild pain in the joints in both knees and mild exfoliation of both palms.

The patient gave no history of previous allergy, either personal or within the family. She had never received any penicillin before.

In these 3 cases there have been certain similarities in the manifestation of the reaction attributed to penicillin. In each case the appearance of the reaction was delayed several days, varying from two to seven, following cessation of penicillin therapy. The first appearance in each was an intense urticaria with severe pruritus and wheal formation, appearing on one portion of the body, either the trunk or the extremities, but rapidly extending to involve most of the remaining cutaneous area. In 2 of the 3 cases there was oedema of both eyelids, causing almost complete closure. Secondly, pain in the joints accompanied by swelling, tenderness, local warmth and painful function were manifested in each case. Malaise with mild fever and tachycardia were also present at this time. A third feature which was present in all 3 cases in the later stages of the reaction was an exfoliative dermatitis of both palms: whether or not this was coincidental or an integral part of the reaction could not be determined, but it was present and was the last manifestation to disappear in each case.

The urticaria responded to treatment with epinephrine hydrochloride administered hypodermically, but it recurred repeatedly and ran a course of approximately seventy-two hours.

None of the 3 patients had had any previous manifestations of allergy in any form, nor were there any other agents to which the urticaria could be attributed.

The characteristic features of this type of reaction appear to be (1) delayed appearance following the cessation of penicillin therapy, (2) intense, severe urticaria, rapidly extending to become generalized, (3) multiple involvement of the joints, large and small, with serous effusion and intense arthralgia, (4) severe malaise, mild fever and mild to moderate tachycardia, (5) exfoliative dermatitis of both palms in the terminal stages as the urticaria fades, and (6) a self-limited course of seven to ten days irrespective of the therapy employed.

Such a composite picture strongly resembles that of serum sickness of the type usually associated with delayed reactions to biologic products such as liver extract, insulin and posterior pituitary injection.

Toxicity of Streptomycin

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 29th June, 1946, p. 745)

NINE patients ranging in age from 15 to 61 years served as subjects. A total dosage of streptomycin of 1.8 million units was administered in divided doses over a period of forty-eight hours or a dosage as high as 72 million units over a period of fifty-six days. Six of the nine patients received the antibiotic by intermittent intramuscular injections at intervals of three to four hours. Two patients were given the drug by continuous intravenous infusion and one by continuous hypodermoclysis. Renal and hepatic function tests were performed just prior to administering the first dose and within ninety-six hours of the final dose. Two additional patients, both desperately ill of tuberculous meningitis, received 3 to 7 million units of streptomycin before death. Post-mortem microscopic examination

did not reveal any liver or kidney lesions that could be attributed to the action of streptomycin. Impairment of hepatic or renal function was not detected by the series of bromosulfate, cephalin cholesterol flocculation and urea clearance studies. Neither was a significant decrease of the haemoglobin or erythrocyte levels encountered in any case.

Although evidence of serious organic toxicity was not obtained, undesirable reactions were recorded with certain patients. These reactions were of two main varieties. The first (2 patients) was characterized by facial flushing, headache and fall in blood pressure, a clinical picture resembling the classic response to histamine. The second reaction (4 patients) consisted of fever, accompanied at times with myalgias and arthralgias. Skin eruptions appeared in 2 patients. Three patients showed slight local reactions consisting of pain and tenderness at the site of intramuscular or subcutaneous injection. The local reaction was alleviated by the local application of heat. Most of the undesirable reactions were apparently related to the amount of impurities retained in the preparations, fewer symptoms being recorded with the latter, more refined preparations of the antibiotic.

The purified streptomycin is thus of such low toxicity as to be freely usable in human clinical medicine.

Vitamin E and Heart Disease

(From the *Journal of the American Medical Association*, Vol. 131, 29th June, 1946, p. 746)

ANNOUNCEMENT in newspapers and particularly in *Time* that large doses of vitamin E will bring relief from all common forms of heart disease once again prompts discussion of the manner in which the results of medical research should be brought to the attention of the public. Far too often of late there has been overemphasis in the popular press on research too fresh from the laboratory and too inadequate as to evidence to permit evaluation. The reported discovery of new and almost miraculous powers of vitamin E needs careful evaluation and confirmation because the substance had already been investigated by many competent clinicians and found wanting. Nothing in the known pharmacologic actions of vitamin E would lead one to suspect either a vasodilating action, a myotonic effect or an ability to repair damaged heart muscle in human beings.

Prediction of Heavy Death Toll from Traffic

(From the *Journal of the American Medical Association*, Vol. 131, No. 9, 29th June, p. 754)

FRANKLIN M. KREML, director of the Northwestern University Traffic Institute, informed the International Association of Police Chiefs board meeting here that in the next ten years the United States will suffer half a million deaths, 15 million injuries and 1½ million crippling injuries through automobile accidents unless a determined programme of traffic control is adopted and followed by the public.

THE PREPARATION OF AN ANTIGEN FROM THE KEDROWSKY'S BACILLUS FOR THE COMPLEMENT-FIXATION TEST FOR KALA-AZAR

A description is given of the technique used for obtaining the antigen from the Kedrowsky's bacillus. This method is applicable for the preparation of similar antigens from other acid-fast bacilli. In the case of the tubercle bacillus, the culture should first be autoclaved to kill the bacilli.

VITAMIN A AND CAROTENE CONTENT OF GHEE (CLARIFIED BUTTER) AND 'FORTIFIED' MARGARINE

1. The total vitamin A activity of ghee prepared from the milk of well-fed cross-bred cows was found to be on the average 36.5 I.U. per g.; carotene contributed approximately 31 per cent of this value.

2. Ghee prepared from milk of buffaloes fed under known conditions had an average vitamin A content of 8.8 I.U. per gramme. In general the addition of green feeds to various concentrates leads to an increase in the vitamin A content of ghee obtained from the milk of the animals concerned. The relation between the period of lactation and vitamin A content of ghee is not marked.

3. Ghee, certified to be genuine, collected from 14 centres in the Madras Presidency contained on an average 8.5 I.U. of vitamin A per g.

4. Twelve samples of blended ghee from the Ghee Heating Centre, Agra, had an average vitamin A potency of 12.2 I.U. of vitamin A per g.

5. A good proportion of the vitamin A activity of ghee, and all the vitamin A activity of 'fortified' margarine, are lost when these are used for frying purposes.

THE DIGESTIBILITY OF CERTAIN VEGETABLE OILS AND FATS DETERMINED BY METABOLIC EXPERIMENTS ON HUMAN BEINGS

The digestibility of certain vegetable oils used for edible purposes in different parts of India, viz, mustard, coconut, sesame and ground-nut oils, of a sample of hydrogenated ground-nut oil (Dalta Varnaspati) and also of cow and buffalo butter-fats (ghee) has been determined by metabolic experiments on four human experimental subjects. It was concluded that the natural fats and oils are almost completely utilized by the human body (94 to 99 per cent) while hydrogenation appears to lower the digestibility to some extent.

THE RATE OF ABSORPTION OF DIFFERENT FATS AND OILS

The rates of absorption of mustard, coconut, olive, ground-nut and sesame oils and of butter-fat have been compared using rats (225 g. to 250 g. weight) as test animals. The fats were fed by the stomach-tube and at the end of definite intervals (2, 4 or 6 hours) the rats were killed, the intact gastrointestinal tract was removed and the fats remaining unabsorbed were determined.

Two hours after administration olive oil and butter-fat were found to be the most rapidly absorbed fats. After 4 hours mustard oil is absorbed to the greatest extent and the others show almost equal rates of absorption. After 6 hours the fats are all almost equally absorbed, the absorption of coconut oil being slightly less than that of the others.

With an increase in the amount of coconut oil administered the rate of absorption of the oil was found to be slightly increased.

THE EFFECT OF DIFFERENT FATS ON CALCIUM UTILIZATION IN HUMAN BEINGS

The influence of the dietary fat on the calcium and phosphorus metabolism in four human subjects has been investigated. Inclusion of mustard, sesame or ground-nut oil or of butter-fat in the diet greatly favoured the absorption of calcium and phosphorus and the utilization of minerals was better than in the absence of added fat. With coconut oil, however, the elimination of calcium through the faeces was greatly increased, the faecal calcium being in three cases greater than the amount of dietary calcium. The urinary excretion of calcium on coconut oil diet was also generally higher than with other fats. The use of coconut oil as the main dietary fat cannot be recommended in view of these findings.

COMPARATIVE VALUE OF BUTTER-FATS AND VEGETABLE OILS FOR GROWTH

Butter-fat fed at 3, 6 and 9 per cent levels to young rats induced maximum growth at the 6 per cent level;

the growth was poor at the 3 per cent level. The difference in growth at the 6 and 9 per cent levels is not significant.

With mustard, coconut, sesame or ground-nut oil or with cow or buffalo butter-fats fed to young rats, all at 6 per cent level, maximum growth—an increase in weight of about 12 g. per week and 2.25 g. per week per g. of fat intake—was obtained with cow butter-fat. The growth with buffalo butter-fat was slightly less. The vegetable oils gave less growth. Of the vegetable oils ground-nut oil gave the greatest (1.79 g. per week per g. of fat intake) and the sesame oil (1.32 g. per week per g. of fat intake) the least growth. Mustard and coconut oils gave a growth intermediate between ground-nut and sesame oils and the difference between mustard and coconut oils was not significant.

DESTRUCTION OF VITAMIN B₁ OF SOME VEGETABLES DURING COOKING AND THE EFFECT OF COOKING ON FREE AND COMBINED VITAMIN B₁ OF SOME FOODSTUFFS

The thiamin retention of thirty-five vegetables after cooking has been determined by the thiochrome method.

A portion of the thiamin content of all the vegetables investigated is destroyed by cooking. The average retention of thiamin after cooking of the vegetables is about 60 per cent.

The percentage destruction of free B₁ and of total B₁ in the case of some foodstuffs has also been studied. It is found that only a portion (50 to 100 per cent) of the free B₁ is destroyed by heat, while the 'bound B₁' or the co-carboxylase portion of the foodstuffs remains practically unaffected.

THE EFFECTS ON GROWTH IN RATS OF BUTTER AND RAGI (*Eleusine coracana*), SEPARATELY AND COMBINED, AS SUPPLEMENTS TO THE POOR RICE DIET OF SOUTH INDIA

1. Butter and ragi (*Eleusine coracana*) were given as supplements in increasing amounts separately as well as simultaneously to young rats on a basal poor rice diet.

2. Butter had a marked inhibiting effect on growth directly proportional to the amount given.

3. Ragi substituted for part of the rice had a marked stimulating effect on growth directly proportional to the amount given.

4. Butter and ragi when given simultaneously exerted their effects independently of each other, i.e. ragi did not counteract the negative effect of butter.

THE ABSORPTION OF FATS FROM THE HUMAN INTESTINE

1. The rates of absorption of butter, ghee, ground-nut oil, partially hydrogenated ground-nut oil, coconut oil and sesame oil from the intestines of healthy human subjects were determined by Frazer's 'chylomicron' technique.

2. Butter, ghee and coconut oil were found to be rapidly absorbed, whereas ground-nut oil and sesame oil were absorbed slowly.

3. Partially hydrogenated ground-nut oil with an iodine value of 50 was absorbed at approximately the same rate as the refined ground-nut oil of iodine value 98.

4. Ghee attained the temperature of 240°C. to 250°C. during frying of *purees*. When such *purees* containing 1 oz. of ghee were eaten, the latter was absorbed at a rate only slightly slower than unheated ghee.

5. It is suggested that the rate of absorption of fat from the intestines is determined among other things by the presence of fatty acids of low molecular weight constituting the fat. Quite a considerable alteration in the iodine value of fat by hydrogenation exerted little influence on its rate of absorption.

OBSERVATIONS ON THE CAROTENOID PIGMENTS OF LOCAL VARIETIES OF YELLOW MAIZE

The composition of 15 different varieties of yellow corn grown in different parts of the Punjab with respect to their different carotenoid pigments has been determined by the method of chromatographic separation and colorimetric estimation. Six different

pigments were detected in the samples examined which were identified as zeaxanthin, cryptoxanthin, β -carotene, α -carotene, λ -carotene, and an isomer of cryptoxanthin called neo-cryptoxanthin.

Varieties of maize varying in colour from moderate-yellow to dark-yellow and deep-red showed the values ranging from 18.76 $\mu\text{g./g.}$ to 40.78 $\mu\text{g./g.}$ for the total pigments.

From the amount of different pigments present the vitamin A potency of yellow corn has been assessed at 6.5 I.U./g. to 9.0 I.U./g. for medium yellow varieties, and 10 I.U./g. to 12.5 I.U./g. for the dark-yellow to the deep-red varieties.

OBSERVATIONS ON THE CAROTENOID PIGMENTS OF THE MANGO FRUIT

The carotenoid content of ten different varieties of mangoes available in Delhi market has been determined by the method of chromatographic separation and colorimetric estimation. Five different pigments have been detected in almost all the varieties examined. Three pigments have been identified, namely, xanthophyll, β -carotene and pseudo- α -carotene. The two other pigments have not been identified. These two pigments also appear to be of hydrocarbon nature.

The various varieties examined showed a total carotenoid content ranging from 30 $\mu\text{g.}$ to 60 $\mu\text{g.}$ per g. of which the active pigments contribute 5 $\mu\text{g.}$ to 40 $\mu\text{g.}$ per g. of the total pigments.

The vitamin A potency has been assessed at 8 to 16 I.U. per g. for poor varieties and 32 to 67 I.U. per g. for rich varieties.

OBSERVATIONS ON THE VITAMIN A CONTENT OF BUFFALO BUTTER-FAT (GHEE)

1. Forty-eight samples of buffalo ghee have been studied for their vitamin A content by the spectrographic method. Out of these, 41 samples were of genuine ghee prepared in the laboratory or in the homes from buffalo milk, while 7 samples were from the market and presumably pure. Twenty samples were found to contain below 24 I.U. of vitamin A per g.; 16 samples showed values between 24 and 30 I.U. and 12 samples above 30 I.U. per g. The average of all the samples taken together was found to be 25.4 I.U. per g.

2. Tests in the laboratory indicated that the process of clarification of butter into ghee ordinarily used in Indian homes is not likely to cause any loss of vitamin A. Prolonged heating at a relatively low temperature causes greater destruction of vitamin A than heating to high temperatures for short intervals.

3. Storing of samples of ghee under ordinary conditions at room temperatures in the summer in Lahore did not result in any significant loss of vitamin A activity during the course of a month. At the end of four months loss varying from 2.5 to 22.5 per cent was noticed in the different samples and after five to six months the loss was between 25 and 30 per cent.

4. The effect of different Indian methods of cooking upon the vitamin A content of ghee was also investigated. In the frying of *purees* 63 to 69.5 per cent of vitamin A was lost. In the making of vegetables and dhal curries, which involve the frying of vegetables and spices in ghee for 22 to 45 minutes, there appeared to be a total loss of vitamin A, while in ordinary cooking in the presence of water the loss was only about 20 to 24 per cent. In *parathas* the loss was only 8.7 per cent and in *halwa* as much as 32 to 39 per cent.

THE EFFECT OF HESPERIDIN AND A FACTOR IN BENGAL GRAM (*Cicer arietinum*) ON THE GROWTH OF GUINEA-PIGS

1. Hesperidin or vitamin P appears to be essential for the proper growth of guinea-pigs.

2. A factor isolated from Bengal gram (*Cicer arietinum*) was found to have a similar growth-promoting effect and may be identical with hesperidin.

STUDIES ON THE DESTRUCTION OF VITAMIN A IN SHARK-LIVER OIL

The influence of moisture, free fatty acids and ground-nut oil on the development of rancidity and destruction of vitamin A in shark-liver oil have been studied using an accelerated oxidation method. Water was practically inert and the increase in free fatty acids during oxidative rancidity was greater in the presence of moisture than in the dry oil. Free fatty acids acted as mild catalysts in the oxidation of the glycerides and the vitamin. The induction period of shark-liver oil, as determined by the formation of peroxides, was increased when the oil was mixed with freshly refined ground-nut oil.

FLUORINE AND DENTAL CARIES IN INDIA

1. The correlation between the incidence in children of dental caries, mottled enamel and fluorine content of drinking water has been studied in various parts of India.

2. A positive degree of correlation between the incidence of mottled enamel and the fluorine content of drinking water was observed which was found to be statistically significant.

3. Statistical analysis showed that degree of severity of mottled enamel was correlated with a higher concentration of fluorine.

4. A lower incidence of dental decay was recorded in 1,765 children showing mottled enamel as compared to 4,312 children showing no mottling of enamel.

5. The severity of mottled enamel had no influence on the caries incidence.

6. In a group of 1,074 healthy adults, who were not living throughout their life in an endemic fluorosis area, no association between the incidence of dental caries and mottled enamel was elicited.

ERUPTION AGE OF TEETH IN INDIA

An attempt has been made to estimate the eruption age of teeth in certain Indian populations. From the data collected in North and South India estimates have been provided for the eruption age of each tooth.

The differences noticed in the eruption ages between boys and girls are not very marked; those between boys of South and North India are also small. Our estimates seem to indicate that in India the eruption of teeth takes place somewhat earlier than in the United States of America.

ANÆMIA AND MALNUTRITION IN INDIAN ARMY RECRUITS

1. An attempt has been made to correlate the blood findings and nutritional status of 801 South Indian army recruits.

2. Anæmia was much commoner in the third of the men whose muscle development was poor than in the two-thirds whose muscle development was moderate.

3. Anæmia was least common in men with poor subcutaneous fat, and most common in men with good subcutaneous fat.

4. There was a clear correlation between anæmia and cutaneous and ocular vitamin deficiency signs.

5. In the more malnourished third of the men an increasing hookworm load progressively added to the amount of anæmia, but no such correlation could be demonstrated in the better-nourished men.

6. Anæmia and splenomegaly were correlated.

7. Most of the anæmia was normocytic and normochromic, but there was usually evidence suggestive of iron deficiency. Macrocytic anæmias were rare and mild.

A FEEDING EXPERIMENT AMONG INDIAN ARMY RECRUITS

1. An experimental dietary survey and feeding experiment was carried out at two Indian army recruit training centres during 1944, over a period of 16 to 20 weeks. The methods used are described.

2. A nutritious diet (the standard Indian army ration), fed to men of the Indian peasant classes, mainly aged about 20 years, caused a gain in weight

amounting to about 5 to 10 per cent of their initial weight within 3 to 4 months. There was also a marked clinical improvement which, however, was not accurately reflected in a record of the incidence of certain specific signs attributed to chronic malnutrition.

3. The addition of 16 fluid ounces of milk to the basic diet did not cause any increase in the gain of weight, but is believed to have accelerated clinical improvement. The latter was manifested particularly in an improvement of skin texture.

A PRELIMINARY STUDY OF THE BIOCHEMICAL CHANGES IN STARVATION CASES

1. Prolonged starvation lowers the blood-sugar level. In some cases figures as low as 0.040 per cent were observed.

2. In certain groups of starvation cases marked lowering of carbohydrate tolerance was observed while in other groups absorption of glucose from the alimentary tract was found to be well below normal.

3. The total serum-protein content of the blood in starvation cases was found to be universally low. This affected the albumin fraction only. In cases with marked oedema the fall in the albumin (as also in the total protein) was sometimes of an extreme degree.

4. The globulin content of the blood was not decreased but was normal or increased. This was particularly obvious in cases with concurrent infection as in the oedema cases.

5. The albumin : globulin ratio was markedly altered. Sometimes, in extreme cases, a reversal of the normal ratio was obtained.

6. Non-protein nitrogen and uric acid were high in the majority of cases. The phospho-lipoid content was found to be exceptionally high in some cases. The cholesterol and the calcium content was found to be low in the majority of the cases.

7. Chloride and urea excretion in the urine was low in almost all cases.

STUDIES ON THE BIOCHEMISTRY OF THE 'CHOLERA-RED' REACTION. PART I

1. The inhibitory effect of glucose on the positive 'cholera-red' reaction in a broth culture has been shown to be due to its reducing influence. Other reducing agents are capable of playing the same rôle.

2. The theory of glucose-tryptophan complex as explaining the failure to obtain a positive 'cholera-red' reaction appears untenable on the basis of experimental observation.

3. The addition of minute amounts of oxidizing agents, capable of undergoing reversible change, can catalytically overcome the influence of reducing agents.

STUDIES ON THE BIOCHEMISTRY OF THE 'CHOLERA-RED' REACTION. PART II

1. Liberation of specific enzyme for breakdown of tryptophan takes place in the presence of glucose. But the formation of the specific end product, which gives positive 'cholera-red' reaction, is prevented in a reducing environment.

2. The enzyme is separable from the cells to a very small extent. It belongs to the class of adaptive enzymes and is heat labile being destroyed on being heated at 56°C. for 30 minutes.

3. A modified technique for the 'cholera-red' reaction has been suggested.

STUDIES ON CARBOHYDRATE METABOLISM

1. The glucose and ascorbic acid contents of blood and inorganic phosphate, potassium, bilirubin and diastase contents of serum were determined in 53 normal persons (31 males and 22 females) and 94 diabetic patients (84 males and 10 females).

2. The relationship between fasting serum inorganic phosphate and fasting blood glucose is definitely altered in diabetes.

3. There is significant inverse relationship between the relative variations in the glucose content of blood

and inorganic phosphate content of serum during the first two hours after the administration of glucose in the case of diabetic subjects. However, diabetics cannot be considered different from normals in this respect.

4. There is no evidence to show that the relationships between the other blood constituents examined are altered in diabetes.

STATISTICAL STUDIES IN GLUCOSE TOLERANCE

1. Statistical analysis of glucose values of fasting blood from 20 normal male subjects between the ages of 18 and 32 shows (i) that the glucose level of fasting blood is affected by variations in body-surface area, but not by those in age and (ii) that there is a high degree of correlation between the glucose levels of blood taken before and after administration of glucose.

2. A multiple regression formula of blood glucose on body-surface area and age is given with a table of estimated glucose values.

PHARMACOLOGICAL ACTION OF AN ACTIVE CONSTITUENT ISOLATED FROM *Dæmia extensa* LINN. (SYN. *Pergularia extensa*). PART I

1. An active constituent of glucosidic nature has been isolated from *Dæmia extensa* in a fairly pure condition, and appears to be toxic to white mice, frogs, guinea-pigs and cats.

2. It has a stimulant action on the involuntary muscles, plain or striated, and a pronounced effect on the circulatory system, raising the arterial blood pressure appreciably.

3. Its action on the uterus appears comparable with that of pituitrin, for which it may prove to be a possible substitute.

4. Its effects appear to be due to (1) the direct stimulation of involuntary muscles, and possibly (2) the stimulation of post-ganglionic cholinergic nerves in the structures concerned.

SECTION OF THE HYPOTHALAMUS TO REMOVE THE HYPERGLYCAEMIC EFFECT OF URETHANE

The most anterior plane through which section is to be made to abolish the hyperglycaemic effect of the hypothalamus passes through the anterior border of the superior corpora quadrigemina above and mamillary bodies below.

THE COMPARATIVE ACTION OF SOME ALKYL HYDROCUPREIDINES

The intensity of action was increased from hydroquinidine and ethyl hydrocupreidine as derivatives higher and higher in the series were tested. The sec-octyl hydrocupreidine behaved a little differently. All these derivatives in adequate doses had a depressing action on the plain muscle of the intestine and the cardiac musculature. The fall of blood pressure was partly due to the depression of the myocardium and partly to the dilatation of vessels of the organs. There was a rise of pulmonary pressure, due to the constriction of pulmonary vessels. Pulmonary oedema was observed with higher members of this series.

STUDIES ON COAGULATION OF BLOOD

1. Certain substances in common use have been found to possess marked anti-coagulant properties.

2. The mode of action of these substances and of some of the well-known anti-coagulants has been studied and classified.

3. A suggestion is put forward that coagulation of blood may be an immunological reaction, with fibrinogen as antibody, prothrombin as complement and any foreign body in association with thromboplastin as antigen.

Activity of a New Antimalarial Agent Pentaquine (SN 13,276)

By R. F. LOEB

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 12th October, 1946, p. 321)

PENTAQUINE (SN 13,276) is 6-methoxy-8-(5-isopropylaminoamylamino)-quinoline.

In all the laboratory and clinical tests, pentaquine has been used in the form of its diphosphate (75.5 per cent base). The salt forms yellow needles which melt at 188–190°C. (402–406°F.) and is moderately soluble in water and slightly soluble in alcohol.

The close resemblance of this drug to pamaquine was observed in experimental animals and in man. It is rapidly absorbed from the gastro-intestinal tract. Plasma levels are quickly attained and decline to zero within twenty-four hours after the drug is stopped. The levels can be fairly well sustained by administering the drug on a four-hour schedule throughout the day and night. There is poor correlation between the dosage and the concentrations of drug in the plasma. Variations in the plasma levels of different persons on a given dosage are often great; but in groups of patients there is a tendency for the plasma level to rise as the dosage is increased. The concentration of the drug in the plasma is usually slightly lower than that which results from the administration of an equivalent dose of pamaquine. Concurrent administration of quinine with pentaquine tends to increase the plasma concentration of the drug to a slight extent.

Conclusions on the toxicity of pentaquine in human beings are based on the results of its administration to 171 white volunteers in dosages from 15 to 180 mg. base per day during the prophylactic and curative tests. At the therapeutic dose, the toxicity of pentaquine is qualitatively the same and quantitatively approximately one half to three-fourths that of pamaquine in adult persons.

Thus 60 mg. of the base administered concurrently with 2 gm. of quinine a day in divided doses for fourteen days is equal in toxicity to 30 to 45 mg. of pamaquine base administered similarly with quinine. At this dosage, the toxic symptoms are occasional anorexia, abdominal discomfort or pain and slight methemoglobinemia (average for 44 patients 4.5 per cent). In limited therapeutic studies of the drug at higher dosages (120 mg. base per day) the toxicity has been considerably greater than that observed with 60 mg. of pamaquine, possibly equal to the toxicity of 90 mg. pamaquine base. In general, the symptoms at higher dosages are qualitatively similar to those which result from the administration of pamaquine; but one symptom which occurred in 2 of 20 subjects, acute syncope due to postural hypotension, and persisted for several months has not been observed after the maximum tolerated dose of pamaquine (90 mg. base a day). It is possible that drug fever may be encountered in a certain number of instances.

Clinical experience with pentaquine has been almost completely restricted to heavy infection with the Chesson strain of *P. vivax* under experimental conditions. The Chesson strain, like other Southwest Pacific strains, is characterized by a high relapse rate. Three types of experiments have been performed:

1. *Prophylactic tests.*—In prophylactic tests, the drug has been administered for eight days to non-immune patients, who are bitten by ten heavily infected mosquitoes on the second day of drug administration. Pentaquine is at least partially effective in preventing the establishment of malaria when administered in toxic dosage (120 to 180 mg. base a day).

2. *Curative tests.*—The primary attacks, the first and the second relapses of non-immune patients inoculated by the bites of ten infected mosquitoes, have been treated for fourteen days. Drugs have been administered every four hours throughout the day and night. Under these conditions, pentaquine will terminate individual attacks but is only partially effective in

preventing relapses when it is administered alone, in dosages as high as 120 mg. base per day; however, when combined with 2 gm. of quinine, the administration of 60 mg. of base a day has led to complete eradication of the disease in 16 of 17 subjects treated. No relapses have occurred in 35 patients treated during their third relapses.

3. *Field type experimental infections.*—In tests of field type experimental infections, volunteers were bitten by ten infected mosquitoes on each of three alternate days, making available extremely heavy experimental infections. In this situation it has been found that the effectiveness of pentaquine is less striking. Sizable percentages of such experimental subjects relapse after the concurrent administration of 60 mg. of pentaquine and quinine for as long as three weeks.

RECOMMENDED DOSAGE

A. *In suppression and prophylaxis.*—The toxicity of pentaquine is too great to warrant its use in prophylaxis or prolonged suppression of malaria.

B. *In cure of malaria due to Plasmodium vivax.*—A daily dose of 60 mg. base (equivalent to 80 mg. of diphosphate) and 2 gm. of quinine administered concurrently in divided doses every four hours for fourteen days is sufficient to produce radical cure of severe infections due to *P. vivax*. The daily dose of 60 mg. base should not be exceeded. Longer therapy may be necessary when non-immune persons have been unusually heavily seeded and have not had previous suppressive therapy. Pentaquine (SN 13,276) should be administered only under close medical supervision, preferably during hospitalization.

Streptomycin in the Treatment of Subacute Bacterial Endocarditis

By W. S. PRIEST

and

C. J. MCGEE

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 21st September, 1946, p. 124)

OCCASIONALLY a case of subacute bacterial endocarditis may be encountered in which the organism is a gram-negative rod insensitive to penicillin. Although a cure may be obtained by the combined use of penicillin and sulphonamides as was true in the boy of S whose recovery is recounted, streptomycin should be the drug of first choice when dealing with such organisms.

Strains of streptococci which are highly insensitive to penicillin may be encountered more frequently. These may be relatively sensitive to streptomycin. Three such organisms were encountered in cultures from a group of 34 patients. One was typically *Streptococcus viridans* after freezing, but was rather atypical in primary cultures of blood. The other two were typical non-hemolytic streptococci. *In vitro* sensitivity to penicillin ranged from 0.8 to 6 units per cubic centimetre. Sensitivity to streptomycin ranged from 0.1 to 1 unit per cubic centimetre. Streptomycin apparently produced sterilization of the valvular lesions in case 1, resulted in negative cultures of blood after penicillin therapy had failed in case 2 and was solely responsible for the cure obtained in case 3.

The dose of streptomycin used, 500,000 units (0.5 gm.) per day, is not necessarily that which will be adequate in all cases in which the use of the drug is indicated. In the 3 cases here reported, serum streptomycin levels of 3 to 12 units per cubic centimetre were obtained.

Unsuccessful Vaccination

(From the *British Medical Journal*, ii, 14th September, 1946, p. 406)

AN unsuccessful vaccination is not proof of insusceptibility to smallpox. A case has been reported recently of a soldier who had been vaccinated no fewer than

HAEMORRHOIDS

*An efficient
therapeutic measure*

When long-standing diseases of the rectum demand surgical measures, and symptomatic relief of pain and discomfort must be provided before surgery can be undertaken, Anusol Haemorrhoidal Ointment provides safe and efficient treatment. It prepares the field for operation and promotes healing afterwards. Anusol Ointment will give

relief in the early stages of the different types of haemorrhoids and other rectal diseases.

Formula : Ol. Theobrom 5.87%, Adeps Lan. 7.88%, Magnesium Stearate 0.50%, Acid Boric 18.38%, Zinc Oxide 10.91%, Kaolin 2.33%, Bism. Subnitrate 1.77%, Bism. Oxyiodogall 2.25%, Methyl Violet B. 0.04%, Ol. Ricin. 3.98%, Bals. Peruv. 3.10%, Paraff. Moll. Alb. q.s. ad. 100.00%.

Anaemia

The administration of a good tonic is of first importance in the successful treatment of the various forms of anaemia. Generally accompanied by loss of appetite, this condition responds to the analeptic action of Waterbury's Compound, a preparation made from a formula containing products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extracts and hypophosphites. It is produced in a palatable form and can be administered with every confidence by the practitioner.

ATERBURY'S COMPOUND

Suture tensile strength and elasticity are of great importance to surgeons who practice the new procedure.

LONDON HOSPITAL ULTRATAN CATGUT
(MORLEY'S PROCESS)
HAS AN AVERAGE TENSILE STRENGTH

28% greater than B.P.C. requirements

and

19% greater than U.S.A. requirements.

(This average is struck from numerous tests before release).

ELASTICITY

The elongation (elasticity) of London Hospital Catgut approximates 40%, giving the necessary expansion to prevent fracture under normal stress.

THE LONDON HOSPITAL LIGATURE DEPT., LONDON, E.1, ENGLAND

VITAPHOR

**indicated in all cases of
VITAMIN DEFICIENCY**

VITAPHOR—the perfect TONIC is standardised to contain the following active Vitamins in each fluid ounce :

B₁ 450 International Units
C 1300 International Units
D₂ 1650 International Units

Without these essential vitamins normal health cannot be maintained. Vitaphor also contains the Glycerophosphate of Sodium, Potassium, Strychnine and Magnesium all combined in a suitable base which gives to this Tonic a pleasant and agreeable taste. Prescribe Vitaphor in all cases of Convalescence from acute illness in cases of undevelopment, faulty Nutrition and all "run down" conditions when the body is in a low state of health.

SMITH STANISTREET & CO. LTD.

CALCUTTA BOMBAY MADRAS KARACHI AMRITSAR LUCKNOW

ten times, always unsuccessfully, during the twelve months before he died of hæmorrhagic smallpox.

True inherited absolute immunity against smallpox, which is but temporary, occurs only among infants born of variolous mothers or of women who have themselves lately undergone successful vaccination. It is not uncommon for primary vaccination to fail to take in a susceptible infant. If a successful result has not been obtained after three attempts at intervals of ten to fourteen days, and if the degree of risk of exposure to smallpox infection warrants some delay, further series of attempts should be made at about three-monthly intervals. In the event of prolonged apparent insusceptibility to vaccinia a change of technique, the use of multiple insertions, and the choice of a different site for the inoculations should be considered; but the operator should not be satisfied until success has crowned his efforts. It goes without saying that the quality of the lymph should be above suspicion.

The Apparently Acute Abdomen in Pulmonary Tuberculosis

By F. E. DE W. CAYLEY

(From the *British Medical Journal*, ii, 14th September, 1946, p. 403)

TWICE in the last three months I have been called to see patients who have been known to have pulmonary tuberculosis and who have complained of abdominal pain of sudden onset and great severity. On examination they both had board-like rigidity of the abdomen with diffuse agonizing pain, and obviously thought their last hour had come. In one case the duty medical officer happened to be of surgical bent and had already called in an anæsthetist to ascertain the patient's fitness for operation, having made a diagnosis of perforated tuberculous ulcer of the bowel. Now in both cases some common features presented themselves. It had been a hot day. Both patients were drenched in sweat as they both had advanced phthisis with high fever, and there is little doubt in my mind that their pain was of a similar ætiology to miners' cramp. I have seen similar abdominal pain in the sweating stage following a malarial rigor, and before I became familiar with the condition, these cases caused me a good deal of worry.

The treatment is table salt given in orangeade, about 2 dram to a pint (8 g. to 568 ml.).

Reviews

STERNAL PUNCTURE: A METHOD OF CLINICAL AND CYTOLOGICAL INVESTIGATION.—By A. Piney, M.D., M.R.C.P., and J. L. Hamilton-Paterson, M.D., M.R.C.S. Third Edition. 1946. William Heinemann Medical Books Limited, London. Pp. xv plus 80, with 12 coloured plates. Price, 15s.

THE idea behind the book is very good which is shown by the popularity it has attained, the copy under review being the third edition. Full justice, however, has not been done to the subject.

The confusion that exists in the minds of the general medical men about erythropoiesis and the nomenclatures used with regard to the different cells has been still more confused. The normal myelogram of the authors differs in no small way from normal myelo-

grams reported by other workers, while myelograms shown under Kala-Azar and Malaria differ markedly from the myelograms seen in these conditions in the Indian subjects. The coloured plates are generally good but the identifying nomenclatures used with regard to some of the cells are questionable.

C. R. D. G.

PRE-OPERATIVE AND POST-OPERATIVE TREATMENT.—Edited by Lieut.-Colonel Robert L. Mason, M.C., A.U.S., and Harold A. Zintel, M.D. Second Edition. 1946. W. B. Saunders Company, Philadelphia and London. Pp. xiv plus 584. Illustrated. Price, 35s.

A new edition is most welcome. When the book appeared in 1937 it was well in advance of anything then in print.

There is again a great deal of recent work assimilated into the body of the various chapters.

Among the names of contributors are many new ones, some of which have been prominent in the journals during the last 8 years. We miss the name of Homans and his beautiful article on thrombosis. Linton's article is excellent and in no way inferior, it is just the absence of an old favourite.

The book is too long to review in detail. Suffice it to say that we have read it with great care and can find no statement which could be said to be unreasonable or impracticable. There is much the experienced surgeon can learn from this book. To the junior surgeon it should provide a constant sound helpmate.

A. T. A.

MANUAL OF DIAGNOSIS AND MANAGEMENT OF PERIPHERAL NERVE INJURIES.—By Robert A. Groff, M.D., and Sara Jane Houtz, B.S. With an Introduction by I. S. Ravdin, M.D. 1945. J. B. Lippincott Co., Philadelphia and London. Pp. xii plus 188, with 111 illustrations. Price, 36s.

THOSE of us who knew the splendid Unit working on the Assam-Burma frontier under the able and stimulating leadership of Brigadier-General Ravdin will remember Lieut.-Colonel Groff and Lieut. Houtz.

This book deserves the highest praise as a complete neat manual on the subject, written on the spot under terrible conditions of climate and hard work. The arrangement of the material is convenient to the needs of the working surgeon and supplies him quickly with all the details required. The diagrams are clear and self-explanatory.

The summary of anatomy at section 14 could have been enlarged with great advantage by the addition of small cross-sections of the limbs. These give the flat diagrams the necessary three dimensional data required so often in difficult dissections for injured nerves.

We recommend the book to all general surgeons as well as those intending to take up nerve surgery.

A. T. A.

CLINICAL HANDBOOK: FOR RESIDENTS, NURSES AND STUDENTS.—By V. M. Coppleston, M.B., Ch.M., F.R.C.S., F.R.A.C.S. Third Edition. 1946. Angus and Robertson Ltd., Sydney. Pp. x plus 459, with 14 figures. Price, 25s.

A CLEAR concise account of Ward work very suitable for students and nurses. As a text for nurses it is excellent. For residents it could have been fuller and more discursive. The text is accurate in so far as it goes.

The fact that the book is now in its third edition speaks volumes for the popularity of a readable simple text amongst nurses and dressers.

Abstracts from Reports

REPORT OF THE RANCHI EUROPEAN MENTAL HOSPITAL FOR THE PERIOD 1ST APRIL, 1945, TO 31ST MARCH, 1946. BY CAPTAIN C. W. E. PETERS, I.M.D. (RETD.), OFFICIATING MEDICAL SUPERINTENDENT. PRINTED BY THE SUPERINTENDENT, GOVERNMENT PRINTING, BIHAR, PATNA

THE number of patients resident in the hospital at the commencement of the year under review was 274 (133 males and 141 females) as compared with 234 (99 males and 135 females) during the year 1944-45. The total number admitted during the year 1945-46 was 313 (287 males and 26 females) as compared with 227 (195 males and 32 females) in the previous year. The admissions included 252 service patients.

The daily average population of patients was 269.13 against 258.50 in the previous year.

Nearly 40 per cent of the patients had neurosis and psychoneurosis. Next, in order of frequency, were schizophrenia, paranoid states, manic depressive insanity, mental deficiency, epileptic insanity, secondary dementia, etc.

The treatment of mental disorders consisted in giving electrically induced convulsion, shock therapy by drugs, pyrexia therapy, hydrotherapy, prolonged narcosis, malaria therapy, occupational therapy and other physical, medicinal or endocrine therapy.

The convulsive treatment definitely cuts short the acute symptoms in early cases, lessens the danger of self-infliction and exhaustion, the nursing difficulties and period of hospitalization. Replacing shock therapy by cardiazol and insulin, it does not induce fear or hostility in the patient. It is more economical and time-saving. No accidents occurred.

R. N. C.

ANNUAL REPORT ON THE WORKING OF THE CIVIL HOSPITALS AND DISPENSARIES IN THE MADRAS PRESIDENCY FOR THE YEAR 1945. PRINTED BY THE SUPERINTENDENT, GOVERNMENT PRESS, MADRAS. Pp. 54. PRICE, RS. 2

Medical relief.—The number of medical institutions in the province at the end of 1945 was 1,182 against 1,194 in the previous year. The number of in-patients treated increased from 410,751 to 424,255. The percentage of deaths to the total number of in-patients treated was 4.53 as against 5.08 during the previous year. Operations increased from 588,063 to 601,783.

The diseases which accounted for the largest number of patients treated in the medical institutions were malaria, scabies, diseases of the ear, ulcerative inflammation, and diseases of the respiratory system other

than pneumonia and tuberculosis. There was an increase in the number of patients treated for enteric fever.

Rural medical relief.—Thirteen dispensaries were opened during the year, bringing the total to 333. Of these, 27 were closed and 9 converted into regular dispensaries, leaving 297 dispensaries at the end of the year. In view of the increase in the cost of living, the Government have sanctioned enhanced subsidy to midwives employed in rural dispensaries.

Tuberculosis.—The total number of patients treated for tuberculosis was 86,407 as against 79,619 in the previous year. The deaths were 1,397 as compared to 1,431 of the previous year. Final year students of the Madras Medical College and the Stanley Medical College, Madras, attended the Tuberculosis Hospital for clinical instruction and demonstrations on recent methods of diagnosis and treatment. Health visitors under training also were given lectures and bedside demonstrations of the methods of nursing in different types of the disease.

Leprosy.—The Madras Provincial Branch of the British Empire Leprosy Relief Association is responsible for the leprosy work in this province. In order to intensify the anti-leprosy campaign, the Government have appointed a specialist as Honorary Director of the Leprosy Research and Honorary Director of the Leprosy Campaign. The Government are financing a Segregation Scheme in the Polambakkan area in Mathuranthakam taluk, Chingleput.

Veneral.—A male social worker was appointed to meet as many of the married patients as possible and persuade them to bring their partners and children for tests and treatment. He has to visit the houses of out-patients also to trace contacts and persuade defaulting patients to continue treatment.

Blood transfusion service.—With the cessation of hostilities the Blood Transfusion Service was continued on a peace basis.

Medical services.—There has been a gradual increase in the cadre strength of the Madras Medical Service with the creation of additional appointments to cope with the increased work in medical institutions and in the special departments of the Medical Colleges and also for special work in connection with famine, epidemics, etc.

The Government have sanctioned the deputation of three officers of the Madras Medical Service for post-graduate study in the United Kingdom and the United States of America in the following subjects during the year:—

- (1) Ophthalmology.
- (2) Chemistry of foods, drugs and forensic chemistry.
- (3) Pharmaceuticals.

Nursing services.—During the year additional nursing staff was sanctioned in the categories of matrons, sister tutors, ward sisters, nurses and nurse pupils. All posts of matrons and sister tutors were raised to gazetted status and a separate category of sister tutors was formed. The compensatory allowances admissible to the several categories of the nursing staff were also enhanced. The Government have sanctioned the deputation of the sister tutor of the diploma of nursing course for the study of Nursing Education at Toronto and Canada, under the Rockefeller Foundation Fellowship. A candidate was selected and deputed to the U.K. for training as probationary nurse under the scheme inaugurated by the Government of India.

Certain philanthropic persons gave donations for the endowment of medals and prizes for nurse pupils every year to encourage them to pass creditably in the examinations.

Medical education.—The University of Madras has instituted post-graduate diploma and higher degree courses in special subjects of Medicine, Midwifery, Surgery, etc., while the Andhra University instituted M.Sc. courses in anatomy, physiology and biochemistry and post-graduate diploma courses in gynaecology and obstetrics, laryngology and otology and ophthalmology, etc.

Buildings.—Owing to the restrictions imposed on the use of steel, iron, etc., major building schemes were not carried out. However, the Government sanctioned the construction of nurses' quarters on up-to-date lines for the King George Hospital, Vizagapatam, and for the Government General Hospital, Madras. The construction of anatomy, physiology and pharmacology blocks in the Stanley Medical College, Madras, the construction of the Central Preliminary Training School for Nurses at Madras and the completion of the extension to the pathology block in the Andhra Medical College, Vizagapatam, were also sanctioned.

General.—With a view to relieve the superintendents of certain Government medical institutions in Madras City and in the mofussil of their administrative and non-technical duties, so that they might have more time for professional and technical work, the Government sanctioned the employment of lay secretaries and treasurers of gazetted rank in some important institutions. The Government are glad to note that, despite adverse circumstances arising out of the war, the working of the civil hospitals and dispensaries has continued to be satisfactory.

Correspondence

ASTHMA AND PNEUMONIA

SIR,—A patient aged 45 was suffering from asthma for the last 15 years. Practically every other day he used to suffer from asthmatic attack. During my treatment he developed pneumonia. He was cured of this by usual treatment. After this attack of pneumonia he is free from asthmatic attack. I hope somebody will try to throw some light over this observation.

Yours sincerely,
HAR NARAIN SINGH,
B.Sc., M.B., B.S.

ABOHR,
23rd February, 1947.

ANTIBIOTICS

SIR,—We have read with interest your editorial of the December 1946 issue, page 538. You have referred to the antibiotic activity of 'Allicin' from *Allium sativum* in the said article. We are sending herewith two reprints for your kind perusal as these might be of some interest to you.

Yours faithfully,
S. N. DUTTA,
Secretary, Bengal Immunity Co., Ltd.

[The two reprints referred to are abstracted below :—

(1) On the Anti-bacterial Activity of *Allium sativum*. By U. P. Basu and P. N. Sen Gupta. *The Antiseptic*, October 1946.

Garlic was washed with water and left overnight spread over a wooden tray. Three hundred such were then picked and the bulbs were macerated and immersed in 9-10 lb. of rectified spirit. The infusion was filtered and the residual mass was again immersed in 5 lb. of spirit for two consecutive days. The whole filtrate was then concentrated under reduced pressure (15-20 mm.).

The residual gummy mass was then dissolved in double distilled water and was subsequently extracted with ether previously washed with dilute alkali solution. The ethereal extract was evaporated in vacuo. The oily residue was washed with petrol ether twice and dried in vacuo over liquid paraffin. This oil was used for anti-bacterial study.

The crude extract itself exerts a bacteriostatic activity against gram-positive and gram-negative organisms.

(2) Anti-bacterial Properties in Chlorophyll. By A. B. Bose and P. N. Sen Gupta. *Journal of the Indian Med. Assoc.*, Vol. XV, No. 11, August 1946, pp. 361-362.

A known amount (80 gm.) of fresh leaves from three plants, viz, *Tagetes patula* Linn. (Beng. Gandha), *Argemone mexicana* Linn. (Beng. Shialkanta), and *Achyranthes aspera* Linn. (Beng. Apang) was washed in water and put in a litre flask containing 200 c.c. of 90 per cent alcohol. It was then kept in a boiling water bath for 2 to 3 hours. The alcoholic extract was then poured in a separating funnel containing 100 c.c. ether. 200 c.c. of distilled water was added slowly down the side of the funnel. The lower layer was run off. The addition of distilled water and subsequent removal of lower layer was repeated four times.

The green and yellow pigments were separated by the following procedure: The ether layer was treated with alcoholic caustic soda (2 gm. NaOH in 25 c.c. calcium). The total solution was then saponified for 18-20 hours. 100 c.c. water was added for complete separation of two layers. The lower green aqueous layer was collected and slowly concentrated on a steam bath to 80 c.c. The pH of the solution was adjusted to 7.6-7.8. It was then filtered through candle. The total chlorophyll (solid) content of this solution was found to be 0.1 per cent approximately.

All three samples were found to exhibit bacteriostatic effect on *Staphylococcus aureus* up to 1:40 dilution. These also inhibited the growth of *Streptococcus hemolyticus* up to 1:80 dilution.—Editor, I.M.G.]

PROGRESSIVE MUSCULAR ATROPHY

SIR,—Mild itching—soreness (with slight epiphora), next the inner canthus in the two eyes, by turn, and a crack-like ulceration at the junction of the skin and mucous membrane in the two sides of the nose alternately—recurrent attacks of these two complaints during December-January last in a case of progressive muscular atrophy was treated and cured with B₁, plinocaine and sulfanilamide mixed with honey. Was it correct to think that these troubles were of a trophic origin?

As to the P.M.A. the case may be described as follows: Vague pains in the left arm were felt during the winter of 1945. He (about 60 years) was used to a dumb-bell exercise ('mudgar'). Gradual weakness followed by some wasting in the left arm. Shoulder muscles attracted the attention in July 1946. Hollows—eminences were felt to the touch; they were not yet quite visible. Injections of strychnine and vitamin B₁ were started in August 4-5 times a week. Progressive atrophy and weakness in the left arm began to cease and decrease but the symptoms now appeared on the other side (in October). This was the time when pains in the previously affected muscles (of the left arm) grew much 'stronger' especially during the intervals between injections. Electric and quake-like shocks were felt specially in hunger and when in very cool atmosphere. These pains grew weaker with the increasing number of injections while the symptoms on the right side continued to develop, until the pains there had assumed the same 'strong' character. This too again after a few days declined and the two arms are now in a much improved and equally good condition needing an injection every 2-4 days. Strychnine has been injected in 1/50 to 1/15 gr. and B₁ in 15-25 mg. doses.

According to Quain—A trophic lesion is a departure from healthy nutrition by the cutting off from certain tissues or parts of some customary nervous influence as in the production of rapid muscular atrophy.

GONDA,
27th February, 1947.

A. OMAR.

[Further observations will be valuable in this case as the disease is rare in India.—Editor, I.M.G.]

Service Notes

APPOINTMENTS AND TRANSFERS

THE VICEROY AND GOVERNOR-GENERAL has been pleased to make the following appointments on His Excellency's personal staff :—

To be Honorary Surgeons

Colonel J. R. Koehlar. Dated 24th November, 1946, vice Colonel R. Lee, vacated.

Colonel S. M. A. Faruki. Dated 4th February, 1947, vice Colonel R. A. Logan, O.B.E., vacated.

Lieutenant-Colonel M. K. Kelavkar, O.B.E., is appointed temporarily as Drugs Controller, with effect from the 4th October, 1946.

The services of Major F. E. Buckler are placed at the disposal of the Director-General, Indian Medical Service, for employment in Viceregal Dispensary, after relinquishing of his Emergency Commission in Indian Medical Service and reversion in I.M.D. (B.C.) now Indian Army Medical Corps (SMS-CC) in his previous status w.e.f. dated 2nd April, 1946.

The undermentioned officer of the Indian Medical Service reverts from the Indian Army Medical Corps and is seconded for service with the Royal Indian Navy :—

Major (T-Lt.-Col.) R. L. Soota, M.B.E. Dated 18th October, 1946.

The Secretary of State for India has sanctioned the reversion to military employment of Major J. Edis Myers of the Madras Indian Medical Service Cadre, with effect from the 17th January, 1947.

Major A. C. Taylor, O.B.E., is appointed Surgeon to His Excellency the Viceroy, with effect from the 28th January, 1947.

Major E. J. Cullen is appointed as Medical Adviser (Pensions), (D.A.D.M.S.), Defence Department (Pensions Branch). Dated 1st February, 1947.

Major M. Ata-Ullah, O.B.E., is appointed as Assistant Director-General, Indian Medical Service (Resettlement), with effect from the 7th February, 1947.

Major V. Srinivasan recalled to duty and posted as Civil Surgeon, Nagpur, from 17th March, 1947.

The services of the undermentioned officers of the Indian Army Medical Corps are replaced at the disposal of the Director of Medical Services in India, with effect from the date shown against their names :—

Captain N. N. Roy. Dated 10th October, 1946.

Captain Harris Haridhan. Dated 13th November, 1946.

Captain S. H. Damle. Dated 14th November, 1946.

Captain H. R. Kherra. Dated 1st December, 1946.

Captain Mulla Mal. Dated 20th December, 1946.

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

To be Lieutenant

J. H. Mason. Dated 11th January, 1945.

LEAVE

The leave of Lieutenant-Colonel W. H. Crichton, Director of Public Health, C.P. and Berar, has been extended up to 31st August, 1947.

Lieutenant-Colonel F. R. W. K. Allen, Civil Surgeon, Amraoti, is granted leave for 4 months with effect from the 10th March, 1947.

Lieutenant-Colonel W. Scott, Civil Surgeon, Nagpur, is granted leave for 6 months from the 17th March, 1947.

Major S. S. Bhatnagar, an officer of the Medical Research Department, was granted combined leave for 16 months (*vis*, war concession leave on average pay for 4 months, and leave on half-average pay for 8 months), with effect from the 5th March, 1946.

PROMOTIONS

Lieutenant-Colonel to be Colonel

J. W. F. Albuquerque, O.B.E. Dated 13th November, 1946.

The undermentioned Indian Medical Service Officer is advanced to the List of Special Selected Lieutenant-Colonels :—

Lieutenant-Colonel M. G. Bhandari, C.I.E. Dated 3rd January, 1947.

Majors to be Lieutenant-Colonels

W. F. Cooper. Dated 2nd November, 1946.

A. N. Duggal. Dated 19th November, 1946.

A. K. M. Khan. Dated 15th January, 1947.

2nd February, 1947

S. S. Bhatnagar. B. Chaudhuri, O.B.E.

H. L. Batra.

A. V. O'Brien. Dated 15th February, 1947.

18th February, 1947

L. Dass. S. M. K. Mallick.

T. C. Puri.

19th February, 1947

C. Mani. R. R. Bakshi.

Captains to be Majors

G. F. J. Thomas. Dated 13th October, 1946.

J. H. Cater. Dated 31st October, 1946.

R. D. Ewing. Dated 1st November, 1946.

O. Walker. Dated 11th November, 1946.

1st January, 1947

G. B. Jackson, C.B.E. C. W. Greene.

W. N. Pennell, O.B.E. T. A. Cunningham.

D. R. Hanbury.

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captains to be Majors

M. N. Menon. Dated 4th May, 1946.

D. K. Bose. Dated 10th May, 1946.

A. D. Iliff. Dated 12th June, 1946.

P. C. Koshy. Dated 25th July, 1946.

H. L. Anand. Dated 18th November, 1946.

A. Sen Gupta. Dated 4th December, 1946.

15th December, 1946

A. P. Diwan. V. V. Ainaपुर.

K. Vullakki. N. Sen Gupta.

Lieutenants to be Captains

J. H. Mason. Dated 11th January, 1940.

G. L. Bawa. Dated 8th October, 1945.

RELINQUISHMENTS

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Lieutenant-Colonel. His services are replaced at the disposal of the Government of Madras, with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Lieutenant-Colonel Dharma Raj Subramania Iyer. Dated 27th March, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Lieutenant-Colonel. His services are replaced at the disposal of the Government of U.P. from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Lieutenant-Colonel M. P. Goel. Dated 2nd May, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Major. His services are replaced at the disposal of the Government of Punjab from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Major Vidya Sagar. Dated 26th October, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Major. His services are replaced at the disposal of the Government of N.-W.F.P. from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Major Aminul Haq. Dated 16th January, 1947.

The undermentioned officer is permitted to relinquish her commission on release from army service and is granted the honorary rank of Major. Her services are replaced at the disposal of the Government of Bihar from the date specified :—

INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

(WOMEN'S BRANCH)

Ty. Major (Mrs.) T. K. Sundaram. Dated 13th August, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Major S. R. Sarma. Dated 24th May, 1946.

Ty. Major A. E. Sundereson. Dated 19th August, 1946.

Major Sachindra Nath Sen. Dated 31st August, 1946.

Major G. H. S. David. Dated 2nd November, 1946.

Ty. Major C. B. D'Silva. Dated 30th November, 1946.

Ty. Major S. D. Malaviya. Dated 11th December, 1946.

Major K. Parthasarathy. Dated 18th December, 1946.

Captain Manakampat Madhavan Unni Nayar. Dated 23rd December, 1946.

Captain Kartar Singh Kalra. Dated 23rd December, 1946.

(WOMEN'S BRANCH)

Major Phanindra Krishna Gupta. Dated 24th May, 1946.

Captain (Mrs.) Isabel Hutton. Dated 5th September, 1946.

Ty. Major Amulya Kumar Saha. Dated 25th September, 1946.

Major T. S. Chohan. Dated 26th September, 1946.

Ty. Major T. D. Gowri Sankar. Dated 30th October, 1946.

Major Trilochan Singh. Dated 11th November, 1946.

Chimanlal Maneklal Kikan. Dated 16th November, 1946.

Ty. Major Babu Ram Mahajan. Dated 14th December, 1946.

Major Mahendra Nath Sen. Dated 20th December, 1946.

Major R. M. Nadkarni. Dated 28th December, 1946.

Ty. Major Thekkethalackal Uthup Poonnen. Dated 30th December, 1946.

Captain Jagjit Singh. Dated 6th January, 1947.

Ty. Major Jayantilal Vithaldas Karia. Dated 11th January, 1947.

The undermentioned officer is permitted to relinquish his commission on grounds of ill health and is granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Major P. V. Krishnan. Dated 27th November, 1946.

Captain J. N. Das. Assistant to Medical Adviser (Pensions), Defence Department (Pensions Branch), relinquished his appointment, dated 4th February, 1947.

The undermentioned officer is permitted to relinquish his commission on grounds of ill health :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain K. N. L. N. Iyengar. Dated 27th August, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of Madras with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain Ramavaram Sreenivasam Kesavaraj. Dated 26th March, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are placed at the disposal of I.G.C.H., Assam, Shillong, from the date specified below :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Major M. K. Ray. Dated 29th April, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are replaced at the disposal of the Government of the N.-W.F.P. with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain S. M. Qureshi. Dated 18th August, 1946.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain Nagarapy Samuel Reddy. Dated 11th November, 1945.

Captain S. K. Misra. Dated 29th April, 1946.

Captain V. S. D. D. 11th May, 1946.

Captain Money. Dated 19th May, 1946.

Captain Mrs. Hannah, E. Kaibre (nee H. Cohen). Dated 20th July, 1946.

Captain T. Karunakaran. Dated 22nd August, 1946.

Captain P. Chandra. Dated 28th August, 1946.

Captain (Miss) Leela Ramchandran (nee M. H. J. James). Dated 31st August, 1946.

Captain R. N. Banerjee. Dated 4th September, 1946.

Captain Jayanty Suryanarayana Rao. Dated 23rd September, 1946.

Captain A. M. Francis. Dated 29th September, 1946.

Captain S. Parthasarathy. Dated 14th October, 1946.

Captain Som Nath Sharma. Dated 16th October, 1946.

Captain Krishna Pillay Mahadevan Pillay. Dated 24th October, 1946.

Captain Abdul Karim. Dated 27th October, 1946.

Captain J. E. Abraham. Dated 29th October, 1946.

Captain P. Krishnamurthy. Dated 29th October, 1946.
 Captain C. M. A. Raza. Dated 2nd November, 1946.
 Captain Tanjore Prasannasimh Row. Dated 3rd November, 1946.
 Captain S. Y. Torne. Dated 17th November, 1946.
 Captain Bimal Chandra Chatterjee. Dated 23rd November, 1946.
 Captain Brijballabh Parshad. Dated 25th November, 1946.
 Captain Nootheti Chinna Venkata Raman. Dated 26th November, 1946.
 Captain J. Ramakrishnayya. Dated 28th November, 1946.
 Captain Sudhansu Bhushan Palit. Dated 4th December, 1946.
 Captain M. Ishaq. Dated 5th December, 1946.
 Captain Daljit Singh Goel. Dated 9th December, 1946.
 Captain Shiv Dev Surie. Dated 10th December, 1946.
 Captain Mani Ram Thapliyal. Dated 13th December, 1946.
 Captain Narayanasami Pillai Sundararajan. Dated 14th December, 1946.
 Captain Homi Bomanji Parehlwala. Dated 16th December, 1946.
 Captain Shridhar Sadashiv Katdare. Dated 19th December, 1946.
 Captain M. Illahi. Dated 20th December, 1946.
 Captain P. C. Reddy. Dated 21st December, 1946.
 Captain J. N. Dhar. Dated 27th December, 1946.
 Captain P. O. Ittooppunny. Dated 29th December, 1946.
 Captain Champaklal Trambaklal Shah. Dated 31st December, 1946.
 Captain M. F. D'Silva. Dated 8th January, 1947.
 Captain A. C. Narula. Dated 16th January, 1947.
 Captain G. T. Joshua. Dated 23rd January, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
 SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain B. Marisiddappa. Dated 1st July, 1946.
 Captain S. K. R. Chaudhuri. Dated 12th August, 1946.
 Captain N. C. Datta. Dated 26th September, 1946.
 Captain P. K. Mukerjee. Dated 10th October, 1946.
 Captain Abdul Ghani. Dated 13th October, 1946.
 Captain A. J. Arungari. Dated 16th October, 1946.
 Captain G. M. Mallesu. Dated 7th November, 1946.
 Captain T. S. Kurup. Dated 10th November, 1946.
 Captain Surendra Gururao Sidenur. Dated 15th November, 1946.
 Captain Amulya Kumar Ray. Dated 19th November, 1946.
 Captain S. N. Dass. Dated 22nd November, 1946.
 Ty. Major V. S. Gopalakrishnan. Dated 22nd November, 1946.

CLINICAL TRIALS OF PALUDRINE*

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
T.D.D. (Wales), F.S.M.F.

Professor of Tropical Medicine

and

M. N. RAI CHAUDHURI, M.B. (Cal.)
Assistant Research Worker

(From the Department of Tropical Medicine, School
of Tropical Medicine, Calcutta)

IN this communication are reported the therapeutic effects of the new synthetic antimalarial drug, paludrine, in certain doses which are specified below. The patients for this investigation were admitted to the Carmichael Hospital for Tropical Diseases. Only those patients whose blood showed malarial parasites in fair or large numbers were selected while those in whom the clinical attack had been of more than a week or in whom any antimalarial drug had been given before admission to hospital were excluded. Four-hourly temperature charts were kept and thick blood films stained by Field's technique were examined twice daily until the blood became negative for asexual parasites and thereafter only once daily throughout the period during which the patients were observed in the hospital unless there was a recurrence of fever or reappearance of parasites when the blood was examined twice daily again.

Of the 80 patients treated 47 had *Plasmodium falciparum*, 30 had *P. vivax*, 2 had *P. malariae* and one had mixed infection (*P. falciparum* and

Dosage

The drug was administered by mouth in tablet form, 100 mg. each. It was temporarily withheld if the patient was having a paroxysm with vomiting, otherwise no special time relationship to the malaria cycle was observed. Suggested schedules of treatment recommended by the manufacturers are numerous and varied. To start with, we chose arbitrarily the dosage of one tablet three times a day for four days, with which 27 patients were treated. Thereafter, we tried single dose therapy and treated 11 with one tablet and 42 with three tablets only in one dose. The object of choosing these single doses was to find out to what extent they can control the clinical attacks of malaria as there is a vast scope for such therapy in the rural areas of India where the mass of the people cannot afford to undergo radical treatment. Thus in this series the following three different courses of treatment were used :—

Regime A—a single dose of paludrine, 100 mg.

Regime B—a single dose of paludrine, 300 mg.

Regime C—one tablet, 100 mg., thrice daily for 4 days (total dose—1,200 mg.).

The scheme of dosage in different age groups was as follows :—

Age in years	Above 12	6 to 12	Under 6
Regime A	100 mg. (1 tablet).	50 mg. (½ tablet).	50 mg. (½ tablet).
Regime B	300 mg. (3 tablets).	150 mg. (1½ tablets).	100 mg. (1 tablet).
Regime C	(1 tablet t.d.s. for 4 days).	(½ tablet t.d.s. for 4 days).	(½ tablet b.d. for 4 days).

vivax). The distribution of patients according to race, sex and age is shown in table I.

*This work was aided by a grant from the Indian Research Fund Association.

Results of treatment

All the 80 patients, whatever the dosage and the nature of their infection, became free from fever and asexual parasites fairly quickly. The

F = *P. falciparum*.V = *P. vivax*.M = *P. malariae*.

immediate effects on the temperature and the parasites are shown in table II.

The average period by which the temperature became normal and the parasites disappeared from the peripheral blood was as follows:—

Regime	Duration of fever	Duration of asexual parasites in blood
A	3 days	2.6 days
B	2.4 "	2.4 "
C	2.5 "	2.3 "

The differences seem slight but they become more noticeable if we follow the results from day to day. It will be seen from table III that while treatment B and C each cleared the parasites in about 11 per cent of the cases in the first 24 hours, the action of A did not become manifest till the second day when it almost equalled the effects obtained in B and C in two days. From the third day onwards the action of the three regimes seemed to depend on the strength of their dosage, being comparatively slow with A, rather quick with C and intermediate with B. In the majority of the cases the parasites had disappeared from the blood within three days—82 per cent in A, 88 per cent in B and 93 per cent in C. The corresponding figures as regards temperature were 73, 88 and 89 per cent respectively. In no case was there any fever or asexual parasite in the blood after the fifth day.

The results are also represented in percentage of total number of cases of each group in the following graph:—

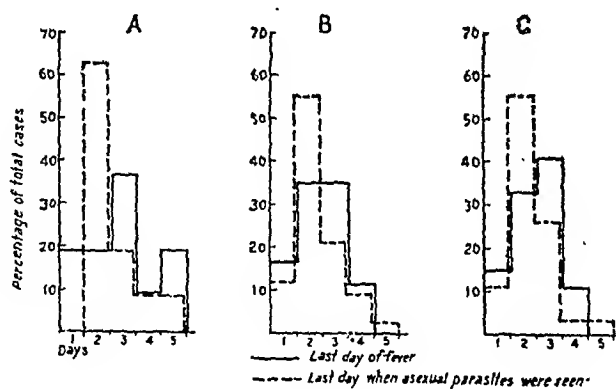

Fig. 1.

The clinical response is illustrated by the following temperature charts (figures 2, 3, 4 and 5).

Another feature that emerges (see tables III and IV) is the markedly parasiticidal action of paludrine on *P. falciparum* on the second day of treatment, whereas in the case of *P. vivax* the action was distributed more or less evenly over the first three days. Actually, by the second day, 77 per cent of the falciparum parasites had been destroyed against 53 per cent of the vivax parasites. Here, too, the extent of their disappearance was dependent on the regimen used, being 71, 77 and 79 per cent under A, B and C respectively in the case of falciparum

infection, whereas the percentages for vivax infection were 50 and 58 under B and C (here we have omitted the A group as having had only too few cases of this type).

Relapses

The study of the relapse rate was somewhat handicapped on account of emergency conditions in the city which prevented us from keeping the patients in the hospital as long as we

Fig. 3.—Effect of single dose of paludrine, 300 mg., on falciparum malaria (regime B, case 10).

had wished. Only 39 patients could be kept under observation from 14 to 30 days, and one patient was for 55 days (table II). Except one all the relapsed patients had fever as well as parasites in the blood.

In group A, of the 8 patients who were under observation, 6 relapsed after an average interval of 14 days (4 falciparum, 1 falciparum and vivax, and 1 malariae). One of them with falciparum infection showed

Fig. 4.—Effect of paludrine, 300 mg., on vivax malaria (regime B, case 14). Asexual parasites were seen on the 8th day of disease—not shown in figure.

parasites in the blood but developed no fever. The actual intervals between the cessation of fever and the occurrence of relapses in the six cases were 4, 8, 15, 18 and 19 days. Figure 6 shows the temperature chart of case 8 with falciparum malaria relapsing after 15 days.

A patient with *P. malariae* infection was treated with regime A (case 10). The duration of fever was 5 days and asexual parasites were seen in blood for 4 days. He had a relapse after 18 days (see figure 9) which was treated with regime C.

In group B, of the 22 patients under observation, 6 relapsed (5 falciparum and 1 vivax) after an average interval of 15 days, the actual intervals being 8, 21, 21, 3 and 10, 20 and 15 days. Figure 7 shows the temperature chart of case 2 with falciparum infection relapsing after 8 days. One of these patients (case 18) appeared resistant to this therapy.

A Mohammedan male, aged 35 years, an employee of this institution, was admitted to the hospital with fever and rigors for 3 days but without any vomiting. Blood showed *P. fal-*

Fig. 5.—Effect of paludrine, 100 mg. t.d.s. for 4 days, on falciparum malaria (regime C, case 6).

Fig. 6.—Falciparum malaria (regime A, case 8). Relapse after 15 days.

ciparum rings. After a single dose of 300 mg. of paludrine the temperature became normal on the 3rd day but the parasites, after a temporary absence for 24 hours (see figure 8), reappeared followed by recurrence of fever. The same dose of paludrine was repeated and he became fever-parasite free in 2 days. Ten days later he had another relapse which was 'successfully' treated with regime C.

In group C, none of the 9 patients (6 falciparum, 2 vivax and 1 mixed) while under hospital observation had any relapses.

To summarize, in a series of 39 patients kept under observation from a fortnight to a month or longer, 12 relapsed, viz, 6 out of 8 patients in group A (85.7 per cent) and 6 out of 21

Fig. 7.—Falciparum malaria (regime B, case 2).
Relapse after 8 days.

patients in group B (29 per cent), while the 9 patients in group C remained free. They were all cases infected with *P. falciparum* excepting one of *P. vivax* and one of *P. malariae*. There

Fig. 8.—Falciparum malaria resistant to regime B (case 18).

were two noteworthy relapses or recrudescences, one after 4 days of apparent clinical cure with regimen A and another after 3 days following the regimen B.

Effect on gametocytes

Gametocytes were present in the blood of 36 patients before treatment was started and they appeared in the blood of 33 patients during and after the treatment. Paludrine had obviously no effect on them. Mosquitoes were fed on two patients with crescents in the blood 4 and 5 days after treatment. Subsequent dissection of these mosquitoes in the entomology department of the School revealed no growth of the parasites in them.

Toxic action

No untoward effect was observed in any patient which could be attributed to the drug.

But it is worth mentioning that one patient with chronic malarial splenomegaly, not included in this series, who was having 2 tablets of paludrine thrice daily; complained of severe pain in the abdomen on the fifth day. He then left the hospital.

Summary

1. Paludrine has an action on an attack of malaria comparable to that of quinine or mepaerine. Trials were given to three different courses of treatment, viz, (A) a single dose of 100 mg., (B) a single dose of 300 mg. and (C) 100 mg. three times a day for 4 days. The average duration of fever with (A) was 3 days and with (B) and (C) about 2½ days. The average period of asexual parasites in the blood was 2.6 days with (A) and 2.3 days with (B) and (C).

2. The asexual parasites disappeared from the blood of the majority of patients within three days—in 82, 88 and 93 per cent under regimens A, B and C respectively. The corresponding figures for temperature were 73, 88 and 89.

3. The drug acted more quickly on the falciparum than on the vivax parasites.

4. It had no action on the gametocytes.

5. Thirty-nine patients were kept under observation for a fortnight to a month (55 days in one case). Twelve of them had relapses which were very common (85.7 per cent) in group A and less so (29 per cent) in group B. There was no relapse in group C. Most of the relapses were cases of falciparum infection.

Conclusion

The small number of cases in our series and the short period of observation would not justify us in drawing any conclusions beyond stating that we feel that the single dose of 100 mg. was an unsatisfactory mode of treatment, as far too many relapses occurred after it. The single dose of 300 mg. was however more

Fig. 9.—*P. malariae* infection treated with regime A: Relapse after 18 days treated with regime C.

promising, but the dosage of 100 mg. thrice daily for 4 days was more effective than either of the other two. The rationale of single dose treatment is first to control the acute attacks of malaria as quickly and conveniently as possible and then to give weekly or bi-weekly doses for

an indefinite period in order to prevent relapses (incidentally also as a prophylactic). Paludrine controls the acute attacks even with one dose of 100 mg. though this dose is not recommended in practice, and it remains to be seen whether it can prevent relapses by repeating it at regular intervals. This investigation will be carried out as opportunities arise.

Acknowledgment

We are grateful to Lieut.-Colonel C. L. Pasricha, I.M.S., Director of the School, for arrangement of special facilities and to Dr. H. Chakravarti and Mr. C. L. Mitter of this department for valuable assistance. Our thanks are also due to Dr. D. N. Roy, Professor of Entomology, for feeding mosquitoes on two patients and their subsequent dissection, and to Messrs. Imperial Chemical (Pharmaceutical) Limited, for a free supply of paludrine hydrochloride.

CLINICAL TRIAL OF PALUDRINE IN MALARIA

By J. G. PAREKH, M.B., B.S., M.R.C.P.

and

B. P. BOGHANI, M.B., B.S.

(Sir J. J. Hospital, Bombay)

A SUPPLY of paludrine for tests on malaria cases was made available to the Superintendent, Sir J. J. Group of Hospitals, Bombay, by the Director of the Malaria Institute of India. The authors carried out a series of clinical trials on confirmed cases of malaria from among patients of this hospital. This is perhaps the first report on tests carried out at Bombay on paludrine. In the present series, 50 cases were treated with different doses of paludrine. Only such cases were taken up for these trials as showed a typically clinical picture of malaria, confirmed by the presence of malaria parasites in the peripheral blood. After selection of the case, at least one paroxysm of fever was allowed to recur before the administration of paludrine. No other antimalarial drug was administered to these patients. Records were maintained of the temperature, occurrence of paroxysms and presence of malaria parasites in the peripheral blood.

This series of observations consisted of trials on 26 cases of B.T. infection, 20 cases of M.T. infection, 3 cases of quartan infection and one case of mixed M.T. and quartan infections.

The different dosages tried in this series are as follows: (i) 100 mg. of paludrine, single dose, (ii) 300 mg. in a single dose, (iii) 100 mg. once daily, (iv) 100 mg. once weekly, (v) 100 mg. thrice daily, and (vi) 200 mg. thrice daily. The cases treated under these dosages are tabulated in table I. The therapeutic efficacy of the drug was gauged by its effect on pyrexia, paroxysms and the occurrence of asexual forms of malaria parasites in the peripheral blood. Twenty-five cases (nos. 1 to 25) were followed up for periods of three weeks to 9 months with a view to observing if any relapses occurred. In

regard to the other 25 cases such follow-up was not possible owing to disturbed conditions in the city of Bombay at the time of this enquiry.

In the majority of the cases treated, it was observed that the single dose of 100 mg. paludrine was effective in bringing down the pyrexia and ameliorating the clinical symptoms. Ordinarily, the temperature came to normal within 24 hours; less frequently, the fever continued for 2 to 4 days. In one case of M.T. malaria, the fever continued for 9 days after the first administration of paludrine. It was generally observed that if the drug was given when the patient had pyrexia, the temperature reached the normal within 24 hours. If given during the afebrile period, either the next paroxysm was aborted or the attack, if it occurred, was of a comparatively mild type. In most of the cases treated, a second paroxysm did not occur, unless a relapse occurred after an interval of several days or weeks.

The different doses tried gave clinical cures in 48 out of 50 cases. From the small numbers of cases treated under the different dosage schemes, it is difficult to say which of these was the most effective one. Two cases of M.T. malaria of the cerebral type (nos. 46 and 47) did not respond to single dose treatment of 300 mg. paludrine; the patients died in four to six hours after administration. In such cases, paludrine does not appear to act sufficiently quickly to control the clinical condition.

In the majority of the cases treated, the asexual forms of the malaria parasite disappeared from the peripheral blood in one to three days after administration of paludrine and remained free from asexual forms unless a relapse occurred. In one case of M.T. infection, however, asexual parasites persisted in the peripheral blood for six days after the initial dosage (case no. 39). In contrast to the rapid disappearance of asexual parasites from the peripheral blood that generally followed the administration of paludrine, it was observed that the gametocytes of all the three species of malaria parasites persisted in the peripheral blood for prolonged periods, ranging from 4 to 20 days. In one case of B.T. infection (case no. 1), gametocytes persisted for as long a period as 90 days. Besides the persistence of gametocytes in the peripheral blood, a definite increase in the number of gametocytes was observed in many cases.

Out of 25 cases that were followed up, relapses occurred in seven cases. One case of M.T. malaria, treated with a single dose of 100 mg. paludrine, relapsed after 12 days (case no. 25). Three cases of B.T. malaria treated with 100 mg. weekly for 2 to 4 weeks relapsed in 2 to 3 months and one case of B.T. (case no. 1), treated with the same dosage for nearly six months, relapsed 2½ months after cessation of treatment. In the latter case, the attack may be due to a re-infection, as the person lived in a malarious area. One case of B.T. malaria

(case no. 22) that received 100 mg. paludrine daily for 8 days, relapsed after 3 months. Another case of B.T. malaria (case no. 2)

treated with 100 mg. thrice daily for 3 days relapsed after six months. Except for these seven cases, none of the other 18 cases followed

27	M.T.	3,000	3	"	
41	M.T.	3,000	2	"	

up had any relapse and all of them remained free from asexual malaria parasites in the peripheral blood for the period that these cases were under observation.

Certain untoward symptoms were observed in six of the cases that received paludrine treatment. These symptoms were weakness, drowsiness, urticaria, vomiting and diarrhoea. In one case, the patient developed back pain, urticaria and desquamation. Another case had urticarial rash combined with drowsiness. The symptoms observed are set out in table II.

TABLE II

Case number	Dosage, mg.	Total drug administered, mg.	Untoward symptoms observed
3	100 weekly	600	Weakness and drowsiness.
4	100 t.d.s.	900	Back pain, urticaria and desquamation.
15	100 "	3,000	Diarrhoea.
19	200 "	1,800	Vomiting and diarrhoea.
20	100 "	1,500	Urticarial rash and drowsiness.
21	100 weekly	200	Weakness and drowsiness.

The occurrence of untoward symptoms showed no relation to the dosage of the drug. The symptoms appeared to be due to personal idiosyncrasies or individual susceptibility to the drug.

Although it is admitted that the number of cases treated in this series is too small to justify any broad conclusions, the results would show that paludrine is at least equal, if not superior, to other antimalarials in bringing about a clinical cure.

Acknowledgments

The authors are greatly indebted to the Superintendent, Sir J. J. Group of Hospitals, Bombay, for the facilities generously offered to them in this investigation. Thanks are also due to the Honorary Physicians of the Hospital who permitted their cases to be treated with paludrine.

PRELIMINARY REPORT ON A NEW SYNTHETIC ANTIMALARIAL

By A. T. W. SIMEONS, M.D.

Director of Health Services, Kolhapur State

and

K. D. CHHATRE, M.B., B.S.

Assistant Director of Public Health, Kolhapur State

IN June, 1946 the Parke Davis Research Laboratories sent one of us (Simeons) a new compound which they called 'Cam-Aqi' for a clinical investigation of its antimalarial properties.

The new compound is 4(3' diethylaminoethyl 4'-hydroxyanilino)-7-chloroquinoline dihydrochloride dihydrate, a yellow crystalline powder of which one gram dissolves in 5 c.c. of water at 25 degrees C.

STRUCTURAL FORMULÆ OF:—

(I) "Cam-Aqi"

(II) Atabrine

The Parke Davis Research Laboratories furnished us with all the relevant data of their laboratory investigations. These showed that in avian malaria this compound is several times as effective as quinine and quinacrine (atabrine). The absorption from the gastro-intestinal tract is very rapid and high plasma levels are established in a short time. In laboratory animals the acute toxicity is about the same as that of atabrine, but in prolonged administration it was found to be only one-fourth to one-half as toxic depending to some extent on the animal species. The toxic symptoms in animals were found to be anorexia, vomiting, spasticity, clonic convulsions and death of respiratory failure; but the quantities necessary to produce such symptoms by prolonged administration in animals were several times greater than in the case of atabrine.

Though asked by the manufacturers to compare this new drug with other antimalarials in the clinic, it seemed to us from a study of the laboratory protocols given to us, that if this compound showed, in man, the low toxicity, the high therapeutic value, the rapid establishment of a high plasma level and the slow excretion observed in laboratory animals, it might, at last, be a real answer to the search for a drug with which all forms of malaria could be satisfactorily treated with a single oral dose. Instead, therefore, of making a comparative study we decided to investigate this possibility first.

As a starting point we chose arbitrarily a single dose of 10 mg./kg. body-weight.

We gave this dose to a series of 50 patients suffering from a clinical attack of malaria. Of these 39 were vivax and 11 falciparum infections. The patients were hospitalized, temperatures were recorded two-hourly. For the first 48 hours they were given only one tablet of ascorbic acid three times daily as a placebo. Parasites were visualized by the thick drop stained by the method described by one of us (Simeons, 1942). The blood was always examined again immediately before giving the single oral dose of the new drug and thereafter at regular intervals ranging from $\frac{1}{2}$ to 4 hours until complete and permanent clearance of peripheral blood was achieved. Falciparum crescents, when present at the time of giving the drug, were in no way influenced. This was to be anticipated from the structure of the compound.

It remained to establish whether in malignant malaria the formation of crescents could be suppressed in such cases as had no crescents at the time of giving the oral dose. All crescent-negative malignant cases were, therefore, examined regularly over a period of several weeks after the blood had been cleared of schizonts. In no case could we detect crescents appearing after the schizonts had been eliminated from the peripheral circulation. As their appearance after treatment with atabrine is a frequent and regular occurrence the new compound would appear to be decidedly superior in this respect. If the observation that the formation of crescents is suppressed while existing crescents are not affected is confirmed this would suggest an extraerythrocytic point of attack.

Clinical results

In all the 50 cases, mostly very heavy infections with parasites ranging up to 200 per oil-emulsion field in the thick drop, the clinical response to a single dose of 10 mg./kg. was dramatically sudden. The temperature chart appears to depend on the phase of the parasite cycle in which the dose is given. In no case did the temperature persist longer than 48 hours. When the dose was given between two rigors there was one further rise after which the temperature dropped to normal. When the dose was given at the height of the temperature or during its declining phase there was usually a rise between 100°F. and 101°F. on the following day. In some cases we noted an uninterrupted lytic fall of temperature spread over the next 36 hours. The average time required for the temperature to subside completely was 28 hours in the vivax cases and 27 hours in the M.T. cases, the difference being statistically insignificant.

The permanent clearance of the peripheral blood—excepting crescents which happened to be present at the time—ranged from a few hours to a maximum of 46 hours in B.T. and 40 hours

in M.T. The average clearance time was 23 hours for B.T. and 25 for M.T. cases.

Relapses

It is still too early to arrive at any definite conclusion regarding the relapse-rate after this single oral dose treatment. However, it is significant that so far not a single relapse has come to our notice in this series during a period of 3 months and more although we decided from the outset to count every clinical case of malaria occurring after treatment as a relapse even if it might have been a re-infection. The patients were all from the Kolhapur State Forces and therefore under continual observation. Though regular blood controls, at first daily and later weekly, were made not a single 'parasite relapse' was seen.

Toxicity

No toxic effects whatsoever came to our notice though very carefully searched for. The dose of 10 mg./kg. was given to a number of non-malarial cases suffering from advanced cardiac failure, cirrhosis of the liver, severe anaemia, advanced bilateral tuberculosis, typhoid and nephritis. In none of these cases could any effect, attributable to the drug, be detected. In no case was there a discoloration of the skin.

The dose

As the arbitrarily chosen dose of 10 mg./kg. showed such favourable results, further series with smaller doses were studied. In a series of 16 cases of which 10 were B.T. and 6 M.T. infections 7.5 mg./kg. was given. The average duration of temperature was 25 hours in B.T. and 35 hours in M.T. cases. No B.T. relapses were observed in this series, but among the 6 M.T. cases 2 relapses occurred both exactly 20 days after treatment. In this series a subnormal temperature was reached in an average of 25 hours in B.T. cases and 35 hours in M.T. cases. The average time required for the permanent clearance of the peripheral blood was 25.5 hours in B.T. infections and 35 hours in M.T. infections.

In order to see whether these less satisfactory results became progressively worse with a further decrease in dosage 17 further cases of which 8 were B.T. and 9 M.T. were treated with a single oral dose of 5 mg./kg. In this series 2 relapses occurred among the B.T. cases, one after 28 days and the other after 5 days, while 7 relapses occurred among the 9 M.T. cases after a period ranging from 10 to 30 days. In this 5 mg./kg. series the clearance of the peripheral blood took an average time of 32.5 hours in B.T. and 32 hours in M.T. infections. The average time required for the temperature to subside was 35 hours for B.T. and 41 hours for M.T. cases. These results are shown in the table.

Table showing the results observed with a decreasing single oral dose of 'Cam-Aqi'

Dose, mg./kg.	Number of cases		Relapses observed		Average time required for the			
					clearance of peripheral blood (in hours)		temperature to subside (in hours)	
	B.T.	M.T.	B.T.	M.T.	B.T.	M.T.	B.T.	M.T.
10	39	11	Nil	Nil	25	23	28	27
7.5	10	6	Nil	2	25.5	35	25	35
5	8	10	2	7	32.5	32	35	41

Thus it seems that 7.5 mg./kg. is sufficient to produce results equal to the 10 mg./kg. dose in B.T. but that in M.T. 7.5 mg./kg. is insufficient. These observations show a generally progressive increase in the time required for the peripheral clearance and the subsidence of the temperature and a regular increase in relapses with diminishing doses. We concluded that 10 mg./kg. was the minimum effective dose which would produce satisfactory results in both types of malaria and abandoned further work on the smaller dose although even the smallest dose of 5 mg./kg. appeared perfectly sufficient to control the clinical attack in every case.

A few cases were studied with a dose of 15 mg./kg. It appeared from these cases that this dose shortened by a few hours both the clearance time and the duration of fever, but this advantage did not seem to us sufficiently marked to compensate for the higher cost of treating patients with the 15 mg./kg. dose. As the 10 mg./kg. dose continued to show perfectly satisfactory results, we abandoned, for the present, a further investigation of higher doses. We must, however, mention that even in the 15 mg./kg. cases not the slightest evidence of any toxic results was observed.

A blanket treatment

In order to study this new compound in children we selected a Mission School Hostel with 110 inmates. During the preceding months there had been a considerable loss of attendance due to malaria—the diagnosis had been confirmed by a blood examination in every case—ranging up to 20 absentees per day. During the preceding month there had not been a single day without malaria absentees. Every child in this hostel was given a dose ranging from 5 to 7.5 mg./kg.—judged visually, not by actual weighing—all the children returned to their classrooms and none showed any untoward effects. On the following day 2 children who were actually suffering from fever at the time of treatment remained absent, on the 2nd day one of these children was absent and from the 3rd day onwards no further case of malaria occurred among these children for a period of 2 months.

The children then left the hostel for a short holiday and when they returned 2 children were found to be suffering from malaria. Both these cases had had malaria previously and can, therefore, be regarded as relapses, but both had had very small doses—one aged 17 had had a total of 200 mg. while the second case aged 12 had had only 100 mg. Both these relapses were treated with a full 10 mg./kg. dose. Apart from these 2 relapses no case of malaria has occurred during a period of over 5 months.

In the same school 116 day boys were given approximately 10 mg./kg. at a later date as among these too there had been a considerable absence due to malaria. During the following two months no case of malaria occurred in this group. None of these children showed any toxic symptoms.

In all 314 persons have been given the new drug without any ill effects. Unless further experience reveals contra-indications or idiosyncrasies which we happened to have missed, this compound can be considered non-toxic in the dose we have used.

We were unfortunately unable to observe the effect of the drug in quartan malaria but we can say that in our small series of B.T. and M.T. cases we found a single oral dose of not less than 10 mg./kg. to be at least as effective as a full course of treatment with any antimalarial known to us.

Field dosage

For practical field purposes it is obviously inconvenient to calculate the dose on body-weight. Messrs. Parke Davis supplied us with 50 mg. tablets. We suggest that 0.2 gm. tablets, grooved for halving, would be most convenient. For such tablets we would suggest the following schedule:—

Infants up to 2 years	..	$\frac{1}{2}$ tablet	0.1 gm.
Children from 2-5 years	..	1	0.2 gm.
Children from 5-14 years	..	$1\frac{1}{2}$ tablets	0.3 gm.
Average South Indian adults	2	"	0.4 gm.
Tall or heavy adults	..	3-4 "	0.6-0.8 gm.

If our findings are confirmed by other workers and in much larger series than we have so far been able to collect this new compound would represent a very real advance in malaria therapeutics as the advantages of a safe, single, oral dose treatment particularly for rural populations are too obvious to require elaboration.

A CLINICAL STUDY ON PALUDRINE

By M. N. DE, M.B., M.R.C.P. (Lond.), F.N.I.

Professor of Medicine, Medical College, Calcutta

and

PRAMATHA NATH DUTTA, M.B.

House Physician, Medical College Hospital

(From the Department of Medicine, Medical College Hospital)

CLINICAL trials with this new drug were carried out in the ward of the senior writer

only on those patients whose blood showed malarial parasites. It was administered in various doses and the effects on the clinical course and also on the parasites were observed from day to day. Blood films were examined at intervals of 24 hours.

Altogether 58 cases were treated of which 20 had M.T. and the rest B.T. infection. None was given any antimalarial drug before admission

into the hospital. This study included 4 groups of cases having 4 different dosages.

Group 1 (vide table I).—In this group, there were 12 cases (4 M.T. and 8 B.T.). Paludrine was administered in doses of 1 tablet three times daily for 7 days and then twice daily for another 7 days. The patients were kept under observation for 2 to 3 weeks after the drug was discontinued and on discharge they were

instructed to return immediately if they got any fever.

The parasites disappeared from the peripheral blood after 48 hours in 7 cases, after 72 hours in 4 cases and after 96 hours in 1 case only. The temperature became normal after 12 to 80 hours of treatment. All these patients felt so much well within 3 to 4 days that some of them insisted on going home or returning to work. They were however detained for our investigation until the full course of treatment was completed. No sign or symptoms suggesting any toxic effect was noticed.

Group 2 (vide table II).—In this group consisting of 20 cases (6 M.T. and 14 B.T.) paludrine was given in doses of 1 tablet 3 times daily for 7 days the observation period being the same as in the first group.

Two patients (nos. 4 and 6) were admitted with severe toxic symptoms and one of them (no. 4) was in a semi-conscious state. Parasites disappeared from the blood after 24 hours in 2 cases, after 48 hours in 12 cases and after 72 hours in 6 cases. Only in 1 case, parasites disappeared from peripheral blood after taking the tablets for 96 hours. Temperature subsided within 12 to 96 hours.

Group 3 (vide table III).—This consisted of 14 cases (13 B.T. and 1 M.T.). Paludrine was administered in doses of 1 tablet twice daily for 7 days. Parasites disappeared from peripheral blood after 24 hours in 4 cases, after 48 hours in 9 cases and after 72 hours in 1 case; the fever stopped within 24 to 72 hours. In 2 cases; however, the fever persisted for 120 hours. There was no relapse.

Group 4 (vide table IV).—This consisted of 7 cases. Paludrine was administered in doses of 2 tablets 3 times daily for the first 2 days and then one tablet thrice daily for the remaining 5 to 6 days. These were severe cases. The patients showed evidences of toxæmia and 2 of them were definitely unconscious. Blood films showed very heavy infection. Four of the cases were M.T. and 3 were B.T. infection but with high fever, signs of dehydration and drowsy state. Some of these patients were unable to swallow the tablets; in fact they could not be fed at all due to unconscious state. In these cases, the tablets had to be crushed, mixed with fluid and administered through a nasal tube. In 4 cases parasites disappeared from the peripheral blood after 48 hours and in 3 cases after 72 hours. Temperature subsided within 24 to 84 hours. None of them ended fatally and there was no relapse.

Group 5.—These cases were treated by another physician who has very kindly allowed us to publish his records. This group consisted of 5 cases and the course of treatment followed by him was 1 tablet thrice daily for 3 days only.

It will be seen from the above that paludrine is undoubtedly an effective remedy in malaria. It is devoid of a bad taste, has no toxic effects as far as it has been studied and so far it appears to hold out fair prospects of being effective against relapse. The period of observation has, however, not yet been long enough to confirm the last point.

It is obvious from the above records that although parasites disappeared from the peripheral blood within 48 to 72 hours in most cases, it took longer time before the patients became completely afebrile. It stands to reason that paludrine takes longer time to sterilize the blood and the parasites, though not detected in the peripheral blood, may be persisting in the internal organs. It is essential, therefore, to continue administration of the drug for a period longer than what would suggest from blood film examination. Some of the observers (M. N. Afridi) have given paludrine to his patients on trial treatments in 3 different doses, viz, a single dose of 1 tablet, a single dose of 3 tablets and two tablets twice a day for a maximum period of 3 days. It is interesting to note the results of his last regime, viz, that by giving 2 tablets twice a day for 3 days he was able to get a clinical cure in 84 per cent and parasites disappeared from the blood in 80 per cent of his cases. Fever stopped within 3 days in 71 per cent. The same observer states that 5 per cent of his cases got 2nd and 3rd attacks. These results appear to compare well with those of the writers. Perhaps the drug was not pushed enough and this might explain some of his failures and also the relapses.

How far paludrine can be used prophylactically for prevention of malarial infection cannot be definitely stated. This problem requires to be studied much more extensively and also by

different observers independently in different places. Although paludrine sterilizes the blood, such a sterilizing effect appears to disappear as the drug is excreted from the system. After this, the subject once more becomes liable to be infected by the parasites. This is the experience of other observers as well as of the present writers and it is very well illustrated in case 6, table IV, who came in first with B.T. infection and was treated with paludrine in doses of 1 tablet 3 times daily for 7 days and got completely cured. The same patient was again admitted into the hospital 2 months later and this time with severe M.T. infection. The patient was a girl student staying as a boarder in a local school where malaria was endemic for some time.

The administration of the drug in big doses in cases with pernicious symptoms is very interesting. It not only demonstrates that the drug is rapidly absorbed to produce a therapeutic effect but that even a considerable amount of the drug administered rapidly is without any untoward effect. In group 4, a large amount of drug was given, through nasal tube when patients could not swallow, and the results were very satisfactory.

The writers offer their thanks to the Superintendent, Medical College Hospitals, for permission to carry on the work in the wards of the hospital. They are also indebted to the Imperial Chemical Industries, Ltd., for supplying them with adequate quantities of the drug to carry on this investigation.

INVESTIGATION ON A CASE OF FEMINISM*

By P. DE, B.Sc., M.B. (Cal.), F.R.C.P. (Edin.), F.N.I.
and

E. G. MONTGOMERY, M.Sc., M.B., B.Ch., B.A.O.
LIEUTENANT-COLONEL, I.M.S.

*From the Department of Physiology, Medical College,
Calcutta*

THE patient, a young male of between 16 and 17 years of age, was admitted to the Medical College Hospital on 19th January, 1946, with pronounced signs of feminism. He stated that about a year previously he began to suffer from frequency of micturition, with the passage of scanty and high-coloured urine. This was associated with a burning sensation in the urethra. He noticed also that his penis gradually got smaller and was reduced to about half of its original size within three months of the onset of his symptoms. Erection, which

* Read at the Physiology Section of the 34th Session of the Indian Science Congress held at Delhi in January 1947.

previously was normal, now became difficult and emission ceased altogether. Two months later he noticed a small swelling on his right nipple which on squeezing discharged a white viscid fluid. Next day the breast was swollen and painful and from that time both breasts gradually increased in size. He stated also that about the same time he began to suffer from frontal headaches and noticed some defect in his vision.

On examination, the most obvious feature was the well-developed breasts with prominent areolæ. They were firm and of a slightly granular texture on palpation. The areolæ were deeply pigmented. Nipples were flat with well-defined duct openings through which a little whitish viscid fluid could be expressed (figure 1, plate XI).

The patient was a fairly well-nourished individual. His skin was of a lighter shade than normal, fine in texture, smooth, and sparsely covered with fine hair. Axillary hair was scanty, while the pubic hair was feminine in pattern. Subcutaneous fat was more abundant over the chest and buttocks. There were no striæ present, but patchy areas of slight pigmentation showed on the anterior aspect of the left thigh and on the lower part of the abdomen.

The penis and testicles were smaller than normal, the left testicle more noticeably so than the right (figures 2 and 3, plate XI).

The voice was high pitched and feminine. This change was noticed by the patient himself two or three months after the onset of his symptoms.

The patient's general demeanour in hospital was good, though he suffered from occasional hysterical outbursts of weeping.

Pulse and respiration and temperature were normal. No abnormality was found in the chest or abdomen. Blood pressure 120/75 mm. X-ray examination of the skull showed no enlargement of the pituitary fossa (figure 4, plate XI).

Visual acuity, right eye 6/36, left eye 6/60, which did not improve with glasses. No abnormality was seen in the fundus. A scotometer test showed some contraction of the peripheral fields, but the test was difficult on account of the non-co-operative attitude of the patient. The central fields did not appear to be affected. The urine showed no qualitative abnormality. Urea content 0.65 per cent; urea clearance test gave an average value of 79.46 per cent of normal function. Friedman's test was negative. Estimation of the basal metabolic rate gave a value equivalent to 4 per cent, a result within normal limits. The W.R. was negative. Blood count was as follows: Hb. 40 per cent (Haldane), R.B.C.'s 2,100,000, W.B.C. 5,300, neutrophil polymorphs 61 per cent, lymphocytes 32 per cent, monocytes 5 per cent, eosinophils 2 per cent, basophils nil.

Biochemical examination of the blood gave the following results:—

Total protein	..	6.5625	per cent.
Albumen	..	4.8825	"
Globulin	..	1.680	"
N.P.N.	..	18	mg. per 100 c.c.
Urea	..	22	" " 100 "
Uric acid	..	2.1	" " 100 "
Creatinine	..	1.96	" " 100 "
Cholesterol	..	70	" " 100 "
Sugar	..	83	" " 100 "
Chloride	..	496	" " 100 "
Sodium	..	330	" " 100 "
Potassium	..	20.5	" " 100 "

Glucose tolerance test:—

Fasting sample	..	0.076	per cent, urine, no sugar.
1st	"	0.088	"
2nd	"	0.104	"
3rd	"	0.090	"
4th	"	0.088	"

Stool examination (Cambridge):—

Total fat	..	30	per cent.
Unsaponified fat	..	19.6	"
Neutral fat	..	1.4	"
Free fatty acid	..	1.2	"

The result of a fractional test meal is shown in the following graph:—

GRAPH

After a stay of 6 months in hospital the cholesterol content of the blood returned to normal levels (110 mg. per 100 c.c.). Blood sugar 85 mg. and blood chloride 537 mg. per 100 c.c.

Unfortunately, the patient left the hospital before further investigations could be carried out. Extractions of urinary steroids have been made, and these are under investigation.

Discussion

At least two of the important steroids of the suprarenal cortex, viz, progesterone and androsterone, though present in small quantities belong to the group of sex hormones. All these hormones are more or less allied in their chemical structure, and can be divided into two groups,

depending on the presence or absence of an oxygen atom at C II in the steroid nucleus. Corticosterone and dehydrocorticosterone belong to the former and progesterone to the latter.

It is therefore not surprising that abnormality of the sex organs and secondary sex characters should be associated with hypo or hyperfunction of the cortical tissue.

As early as 1855, Thomas Addison described the syndrome now known as Addison's disease. This is due to degeneration, destruction, or deficiency of the suprarenal cortex. Subsequent observations on this condition have shown that depression of sex function is one of its chief features. It is known also that during pregnancy there is enlargement of cortical tissue.

Sexual abnormalities are characteristic features of cortical tissue tumours. Such tumours have been associated with premature sexual maturity in children by Bulloch and Sequeira (1905). Puberty in these children appears prematurely, there is great development of sex organs, and there may be precocious sexual desire.

Adult male subjects of cortical tumours seldom give any evidence of endocrine disturbance. A few only show exaggeration of masculine characters, whereas feminization is more commonly observed. In the latter, atrophy of the testes and penis, enlargement of the mammae, and a feminine distribution of fat are the main features.

We wish, however, to deal with some of the other features of hypo or hyperfunction of the cortical tissue which have a bearing on this case.

In Addison's disease and in other cases of hypofunction of cortical tissue, low blood pressure, low metabolic rate, loss of appetite, hypochlorhydria, decrease in plasma Na and chloride, increase in potassium concentration in plasma, in tissue fluids and in the tissue cells, rise in calcium content of the serum, dehydration and reduction of blood volume, hypoglycaemia, renal insufficiency, rise in blood urea and non-protein nitrogen have been observed.

Loeb *et al.* (1933) noticed an increased loss of sodium salt by the kidneys in experimental adrenalectomy. Marshall and Davis (1916) were the first to show an increase in blood urea and a diminution in renal function by the phenolsulphonephthalein test after removal of the adrenals. The urea clearance was also reduced, and there was an increase in creatinine and non-protein nitrogen in the blood. A fall in the basal metabolic rate has also been observed in the adrenalectomized animal after recovery by Webster, Pfiffner and Swingle (1932).

Thorn *et al.* (1936) have shown that in normal dogs and healthy persons, cortin reduces the excretion of sodium and increases that of potassium. The normal kidney function is restored to the greatest degree by desoxycorticosterone, which reduces the non-protein nitrogen of the blood, whereas corticosterone and dehydrocorticosterone, which possess an oxygen

atom at C II exert the least effect on water and salt metabolism. Desoxycorticosterone, on account of its effect on water and salt metabolism, increases the plasma volume and the sodium concentration in the body fluids, but the potassium concentration is reduced (Loeb *et al.*, 1933).

In normal and in adrenalectomized animals, Britton and Silvette (1932, 1934) have shown an increase in blood sugar and liver glycogen by administration of cortin. These effects are most strongly exerted by corticosterone and dehydrocorticosterone. Ingle (1941) has demonstrated that dehydrocorticosterone in 10 mg. doses a day causes hyperglycaemia and, in normal rats, glycosuria. The hyperglycaemia is due to gluconeogenesis, and there is an increase in the glycogen storage.

Ingle (1941) and Long *et al.* (1940) showed that glycosuria is produced by corticosterone and dehydrocorticosterone, by stimulating gluconeogenesis from protein, but the increase in the excretion of nitrogen is insufficient to account for the amount of glycosuria. It has therefore been surmised that the interference with oxidation of glucose might also be a contributory factor in the production of glycosuria.

From what has been mentioned above, it is evident that desoxycorticosterone exerts its effects primarily on water and salt metabolism and restores the renal function. It has little or no action on carbohydrate metabolism. Corticosterone and dehydrocorticosterone, on the other hand, markedly influence the latter, and have practically no influence on the metabolism of water and salt.

Lovatt Evans (1945) states that after hypophysectomy the inner layers of the adrenal cortex show a considerable atrophy. First the zona reticularis and then the zona fasciculata shrink and degenerate. These atrophic changes can be prevented by injection of adrenocorticotrophic hormone of the anterior pituitary. Injections of these extracts into normal animals produce hypertrophy of the inner layers of the suprarenal cortex. The cortical influence on the metabolism of protein, fat, and carbohydrate is most affected by the adrenotropic factor.

It may be suspected from this that the inner zones of the cortex secrete the hormone concerned with the control of the metabolism of these substances. The outer and newly formed cells of the zona glomerulosa of the cortex may either secrete enough hormone or a hormone of the right type to exercise control over the regulation of salt and water in the body after removal of the pituitary.

It will therefore be reasonable to conclude that the zona glomerulosa is responsible for the production of desoxycorticosterone, and the zona fasciculata and reticularis for the production of corticosterone and dehydrocorticosterone.

Some of the complex symptoms manifested by our patient; *viz.*, increase in sodium and chloride content of the plasma, reduction in urea,

and non-protein nitrogen of the blood, increase in plasma volume and diminution of plasma proteins, efficiently functioning kidneys, normal urea clearance and hyperacidity, are suggestive of hypersecretion of desoxycorticosterone from the outer zone of the adrenal cortex; whereas, the low normal blood sugar level and the increased glucose tolerance of the patient are indicative of hyposecretion of corticosterone and dehydrocorticosterone from the inner zones of the cortex.

It is rather a little difficult to conceive at first sight a primary condition of hyperactivity of the zona glomerulosa with hypoactivity of the zona fasciculata and reticularis of the suprarenal cortex. It is known, however, that hypophysectomy produces a considerable atrophy of the inner layers of the cortex.

In this patient the x-ray examination showed a normal pituitary fossa. Possibly the development of the pituitary proceeded normally till adolescence, when atrophic or degenerative changes started in the anterior pituitary with consequent reduction of its adrenotropic hormone. This produced degenerative or atrophic changes in the inner zones of the cortex, leading to diminished secretion of corticosterone and dehydrocorticosterone. The increased glucose tolerance of the patient lends support to this idea. Possibly there is also a hyposecretion of the growth or gonadotropic hormone, and a condition of sexual dwarfism has been produced, resulting in atrophy of his testes and penis, loss of sex function and fatness.

Some of the adrenal corticosteroids show androgenic or oestrogenic properties, and are similar in chemical structure with sex hormones, desoxycorticosterone has been proved to have a progesterone-like action, and progesterone and androsterone are present in the adrenal cortex.

It has been shown by several observers that a metabolic product of androgens in the body is oestrogen, probably in the form of oestrone. It is to be expected, therefore, that any disturbance of metabolism producing excessive amounts of steroids with androgenic or oestrogenic functions will produce alterations in the sex organs and secondary sex characters, depending on the relative amounts of active materials produced. The urine of this case contained an excessive amount of oestrone (500 I.U. per litre) as indicated by tests on ovariectomized mice, by the smear test introduced by Allen and Doisy (1927). The 4-injection method described by Emmens (1939) was followed.

No treatment was carried out on this patient while in hospital beyond special attention to his diet. After about 4 months' stay in hospital his general condition improved, he had partial restoration of libido, with emission. The improvement is in accord with our opinion that the underlying cause of his condition was a primary degeneration of the anterior pituitary, with hyperplasia of the zona glomerulosa of the adrenal cortex.

A point of some interest is the low cholesterol content of the blood. The physiological functions of this substance are little understood. Blood values may fluctuate considerably during the process of digestion, and they may be high in a number of pathological conditions. Low values are not so frequently seen. Defective absorption may have played a part in this case, but it is more likely that the main cause was a defect in its production from endogenous sources. This is only to be expected in view of the disturbed condition of the adrenal cortex. It is further of interest to note that with the improvement of the patient the blood cholesterol returned to its normal value.

Summary

1. History of a case of feminism in a young adult male, with laboratory findings, has been recorded.

2. The biochemical reports of the patient indicate a condition of hyperactivity of desoxycorticosterone, due to hyperplasia of the zona glomerulosa of the suprarenal cortex, and one of reduced activity of corticosterone and dehydrocorticosterone, due to atrophy or degeneration of the zona fasciculata and zona reticularis.

3. The degeneration of the inner zones of the cortex is due to reduced secretion of adrenotropic hormone of the anterior pituitary.

We wish to express our most grateful thanks to Dr. R. K. Callow who supplied us with literature, to Prof. P. Chatterjee for affording us all facilities for investigation and to Mr. Jagnewar Saha for the photographs.

TREATMENT OF OSTEOARTHRITIS WITH INTRA-ARTICULAR INJECTIONS OF LACTIC ACID

By B. RAMAMURTHI, M.B., B.S.

DISEASES of joints (Sanskrit—Sandhi Vatha) and their manifestations have been well studied in ancient India (and also by the Egyptians). In India there seems to have been an understanding of the difference between the two types of chronic arthritis which we recognize now, namely the rheumatoid or the infective and the osteoarthritis or the degenerative type of the disease. They recognized two types—the one affecting the smaller joints and leading to crippling (Khallee Vatha) and the other 'causing atrophy and hypertrophy'. The symptoms of the latter were described as rigidity, atrophy and hypertrophy, fissuring of the bone, lipping, kyphosis when it affects the spine, fatigue, pain and swelling. The treatment for the latter condition followed the usual line of physiotherapy, application of medicated oils and thermogenic agents and massage and movements. Intake of buttermilk (which has a high lactic acid content and low pH) was stressed very much.

The normal synovial fluid contains about 2,000 cells per c.mm. It contains proteins (a little less than 2 per cent) of which mucin is the most important. The importance of this fluid is that in addition to acting as a lubricant it nourishes the central portions of the articular cartilage. Hence in conditions in which the properties of this fluid get altered we may expect the articular cartilage also to be affected correspondingly.

Normal synovial secretion has the same H ion concentration as blood. In traumatic arthritis it was found that the effusion into the joint had a pH of 5.8 for 2 or 3 days which changed over to alkalinity in about seven days (from 5.8 to 7.8). This was explained by the presence of sarcolactic acid as a fatigue product in the effusion. These joints returned to normality quickly. But in non-traumatic hypertrophic arthritis, the initial pH which was on the acid side 6.6 changed to pH 8 in a few days and remained more alkaline than blood and these joints showed much less tendency to quick recovery. Also, the intra-articular injection of lactic acid in cases of lax joint due to traumatic arthritis restored the functional activity early.

With these facts Waugh (1936) suggested treating rheumatoid arthritis with injections of lactic acid. Finding fairly good results, he also tried in other arthritis including degenerative arthritis of big joints and found good results. He suggested that the acidity excites a polymorphonuclear leucocytosis followed later by local mesoblastic proliferation and this helps in the clinical improvement. Also the change in the pH helps to nourish the cartilage better (though we found that the change in pH lasts only about three weeks).

Crowe (1944) reports on 284 painful joints conditions including osteoarthritis treated with intra-articular injections 1 per cent acid potassium phosphate in isotonic solution. He found lasting improvement in 3/5ths of the patients and temporary improvement in the remaining 2/5ths.

This paper reviews 120 cases of osteoarthritis treated by intra-articular injections of lactic acid in the Orthopaedic Department of the Government General Hospital, Madras, during 1945. This does not include cases of osteoarthritis given physiotherapy, liniments, etc., or operative procedures as arthrodesis, arthroplasty, cheilectomy, synovectomies, and denervation of sensory nerves.

The cases reviewed here were all degenerative arthritis of big joints. The diagnosis was made by the age and the build of the patient, the clinical history, the affections of the big joints, and the nature of the pain (most acute in the morning when the patient gets up and wearing off by noon to come on again with fatigue in the evening) and in many cases the diagnosis was confirmed by x-rays. Diabetes and albuminuria were excluded. Erythrocyte sedimentation rate was not taken in these cases as it was considered that increase in the blood sedimentation rate is not even a fairly constant factor in degenerative arthritis of the big joints.

In a few cases with a little effusion, the pH of the fluid was tested before the injection, 48 hours after the injection and three weeks later. It changed from pH 8 before the injection to 7.2 in 48 hours. In three weeks it was again at 7.8 or 8. For 48 hours at least after the injection the pH was on acid side of blood (i.e. normal synovial fluid pH). In three weeks it came back to original level of pH but the clinical improvement had lasted.

X-rays taken before the injection and after do not show any appreciable change corresponding with clinical improvements.

The joints treated were hip 16, knee 81, ankle 6, shoulder 12, and wrist 5. Of these 10 cases were due to some change in the weight bearing mechanism like genu valgum, old fracture calcaneus, etc.

The methods of approach to the joints were of an orthodox nature and have been described by many. With full aseptic precautions, 15 c.c. of lactic acid of pH 5.4 (prepared by the Madras Medical College Biochemistry Department) with 1 c.c. of novocaine 1 per cent, were injected into the joint. For smaller joints, smaller quantities were given (wrist and ankle 7 c.c., shoulder 10 c.c.). After the injection the joint was moved once through its full possible range of movement. The patient was sent home and allowed to move about. Care was taken to see that the injection was intra-articular as a few cases in which the injection happened to be extra-articular had very severe pain even during the injection.

The immediate sequel in many cases was slight tension and pain in the joint which subsided from 24 to 48 hours. The average time taken for the pain and stiffness to disappear was from 5 to 7 days. In many cases the result was lasting from 8 to 16 months in 50 per cent of the cases. In some a second and even a third injection was required and these were given at fortnightly intervals (in 20 per cent of cases). In bilateral cases one joint was injected 15 days after the other.

The cases where the osteoarthritis was due to some upset of the weight bearing mechanism had only temporary relief. Shoulder joint cases also did not show satisfactory results.

One feature which was noted was that about 20 per cent of patients had very severe pain and swelling of the joint within 2 to 3 hours of the injection. In some cases it was known that the injections were given extra-articular by mistake and these patients got pain during the injection itself. Good results have been reported with peri-articular injections of lactic acid with novocaine, but in the painful cases in our series (20 per cent) the pain came on late, lasted for about three to five days and was very severe; these cases have shown lasting improvement.

The increased range of movement with relief of pain that results from the injection is a boon to the poorer classes of patients as it helps them to squat on the floor as most of our patients were of the working class type.

In a review in the *Medical Annual*, 1946 (p. 303), it is mentioned that the intra-articular and peri-articular injection of novocaine (which is added to the lactic acid) with the movements through which the joint was put to, after the injection, was responsible for the improvement rather than the lactic acid itself. But in the above series the injection of lactic acid was given intra-articular with only a very small quantity (1 c.c. of novocaine) and the joint was moved only once through the full possible range and not as in manipulation of joints. These cases (at least 50 per cent) have shown very good clinical and subjective improvement. We have to infer that the changes in pH of the synovial fluid has something to do with the improvement.

A report on one of the cases.—Kanniammal, a housewife, aged 50, had pain in the right knee with creaking for the past six months. She could not squat on the floor and the pain was very severe in the morning when she got up. The joint was not swollen. There was crepitus present on movement and the last 40 degrees of flexion was not possible. The other joints were normal. The patient tended to be fat. On 18th September, 1945, 15 c.c. of lactic acid with 2 c.c. of novocaine were injected intra-articularly. She had some pain on the day of injection. This disappeared and in a week she was able to squat on the floor though creaking had persisted. Till now she has had no recurrence of pain.

My thanks are due to Dr. N. S. Narasimhan, F.R.C.S. (Eng.), F.R.C.S. (Ire.), Orthopaedic Surgeon, General

Hospital, Madras, for his suggestions and encouragement and to Major Sangam Lal, I.M.S., M.S., F.R.C.S., Superintendent, Government General Hospital, Madras, for permission to publish this report.

SEROLOGICAL TECHNIQUE (contd.)

By S. D. S. GREVAL

LIEUTENANT-COLONEL, I.M.S.

(From the Laboratory of the Imperial Serologist and Chemical Examiner to the Government of India, School of Tropical Medicine, Calcutta)

COMPLEMENT-FIXATION

THE COMPLEMENT

SOME antigen-antibody reactions do not become complete without an aid from the fresh serum. The immunological reagent which gives the aid and completes the reaction is the complement. In giving the aid it is exhausted or fixed: Hence the reaction of complement-fixation. The antibodies needing the complement are amboceptors.

Complement-fixation

(From COMPLEMENT-FIXATION FOR CLINICAL PURPOSES by Lieut.-Colonel S. D. S. Greval, I.M.S.; published by Messrs. U. N. Dhur and Sons Ltd., 15, Bankim Chatterjee Street, Calcutta.)

The complement is present in almost every vertebrate (the mouse is a known exception), but for the purpose of the reaction it is obtained from a guinea-pig. At least three male guinea-pigs are bled, under ether anaesthesia, from the heart, each yielding 3 to 4 c.c. and recovering completely for another yield after a week.

[For the purpose of ensuring a week's rest the animals are divided into batches and each batch coloured distinctively. Six convenient colour schemes are: (1) red entirely, (2) blue entirely, (3) yellow entirely, (4) red right and blue left, (5) red right and yellow left, and (6) blue right and yellow left.]

The blood is collected in a wide mouthed bottle and allowed to clot at room temperature for $\frac{1}{2}$ hour, the bottle lying on its side on a special

stand. The clot is then incised in two places along its length and the bottle left in the cold for a convenient and constant period, so turned that the clot is now in the upper part of the bottle. The clear serum oozing from the clot collects in the lower part of the bottle and is preserved by the cold. Before use the serum is transferred to another bottle and centrifuged (in chilled tubes) if necessary. *It should not be agitated violently at any stage*, beginning with the emptying of syringes into the bottle. The complement-containing serum is called the complement.

The reaction when used in detecting the presence of an antibody by means of a known antigen or the presence of an antigen by means of a known antibody is known as the complement-fixation test. Both terms, reaction and test, are often used interchangeably.

The natural complement present in a serum to be tested is destroyed by heating the serum at 55° to 56°C. for ½ hour or by aging it without freezing. The serum is then *inactivated*.

Apparatus, chemicals, etc., used in complement-fixation reaction: 1. *Apparatus non-expendable.*—1. Refrigerator or ice-box. 2. Autoclave. 3. Oven. 4. Steamer. 5. Water bath at 56°C. 6. Water bath for evaporation. 7. Incubator. 8. Centrifuge. 9. Seitz filter. 10. Racks for tubes, metal and wooden. 11. Stills, copper and glass. 12. Pestle and mortar, glass. 13. Syringes, 20 c.c., 5 c.c., 1 c.c. and needles, steel and platinum. 14. Lumbar puncture needle, platinum. 15. Sahli, haemometer. 16. Glazed jars for digestion with acids. 17. Desiccators. 18. Vacuum pump, etc. 19. Bunsen burners. 20. Spirit lamps. 21. Platinum wire, thick and thin. 22. Chemical balance. 23. Hand lens. 24. Wire gauge (L. S. Starrett Co., U.S.A.). 25. Soxhlet apparatus. 26. Sand bath. 27. Glycerine bath. 28. Condenser. 29. Reflux condenser.

2. *Apparatus, expendable.*—1. Graduated pipettes, 10 c.c. and 1 c.c. measuring to tips. 2. Test tubes, 3 × ½, 4 × ½, 5 × ¾. 3. Measuring cylinders, 1,000 c.c., 100 c.c., 10 c.c. 4. Centrifuge tubes, 10 c.c. graduated. 5. Flasks, 1,500 c.c., 100 c.c. and 50 c.c. 6. Beakers, nests. 7. Stoppered bottles, narrow and wide mouth. 8. Glass funnels. 9. Glass phials, 4 oz. and 1 oz. 10. Filter papers. 11. Filter discs. 12. Glass marking pencils. 13. Plasticine. 14. Cotton wool. 15. Glass wool. 16. Corks. 17. Rubber gloves. 18. Rubber tubing. 19. Glass rods. 20. Glass tubing.

3. *Chemicals.*—1. Iodine. 2. Alcohol. 3. Ether. 4. Acetone. 5. Collodium flexile. 6. Trikresol. 7. Cholesterol. 8. Sodium chloride. 9. Silver nitrate. 10. Sodium citrate.

4. *Cleaning of glassware.*—Details given under HAEMAGGLUTINATION apply.

THE HAEMOLYTIC SYSTEM

It consists of (i) rbc, (ii) an appropriate haemolytic amboceptor, and (iii) the complement. When the three constituents are mixed the rbc are haemolysed. The quantities are so adjusted that a complete haemolysis of the rbc occurs and provides a constant measure of the complement.

The RBC

Usually sheep rbc are used. Whole blood is taken (from the external jugular vein, with sterile precautions, in a record syringe) and diluted with an equal volume of 1.5 per cent sodium citrate in normal saline. It is washed three times. The deposit is measured and resuspended in normal saline to make suspensions of desired strength.

For preparing the haemolytic amboceptor a 50 per cent suspension is necessary (*vide infra*).

For preparing the usual haemolytic system a 6 per cent suspension is prepared (6 c.c. deposit + 94 c.c. saline or smaller volumes similarly made) and standardized colorimetrically. Seven drops of the suspension measured with the standard pipette (delivering 50 drops to 1 c.c.) should give a reading of 51 on Sahli's haemometer, following Sahli's procedure of lysing the rbc. If the reading is higher, proportionately more saline is added to the stock suspension thus:

It is found that the stock suspension measuring 100 c.c. gives a reading of 60; it should be made up to

$$\frac{60 \times 100}{51} \text{ c.c.} = \frac{6,000}{51} \text{ c.c.} = 117.8 \text{ c.c.}$$

The outgoing seven droplets can be ignored.

Smaller volumes are adjusted similarly. If the reading is lower, more deposit of rbc is added to bring it up to 51 or higher.

If the deposit is firm a higher initial reading is more likely.

Other things being equal, a stronger suspension yields a less sensitive haemolytic system: Hence the need for the standardization of the rbc suspension. The method described for the standardization is obviously superior to those depending on coal gas in the laboratory or complicated mathematical formulae.

The rbc are the antigen of the haemolytic system.

The Haemolytic Amboceptor

Amboceptor = both receptors (*vide diagram of complement-fixation*).

A sheep-rabbit haemolytic amboceptor is used. Full grown rabbits (weighing about 3 lb. in Calcutta) are injected in the ear vein with 50 per cent suspension of the rbc, on 3 successive days, thus:

- 1st injection, 1st day, 1 c.c.
- 2nd injection, 2nd day, 2 c.c.
- 3rd injection, 3rd day, 4 c.c.

Four days after the 3rd injection a sample of blood is taken from the ear vein for testing. 0.1 c.c. sucked in a capillary pipette, by means of a rubber teat, suffices. The blood is moved up the stem about 3 centimetres and the end of the pipette sealed quickly over a flame. The clear serum is collected below the clot and inactivated by immersing the stem of pipette in water between 55 and 56°C. for $\frac{1}{2}$ hour. The sealed end is then broken and the serum deposited as a droplet on a clean slide. The inactivated amboceptor-containing serum is called the amboceptor. From the droplet enough serum for a drop measuring $\frac{1}{50}$ c.c. is picked up again in a standard capillary pipette. The following dilutions are prepared, thus :

- (1) 1 standard drop + 2 c.c. saline
from which 1 standard drop
has been removed (in a
 $3 \times \frac{1}{8}$ tube) = 1 + 99
= 1 in 100
- (2) 1 c.c. dil. (1) + 9 c.c. saline
(in a $5 \times \frac{1}{8}$ tube) = 1 in 1,000

The test is performed (in $3 \times \frac{1}{8}$ tubes in a metal rack or $4 \times \frac{1}{8}$ tubes in a wooden rack) as follows :—

Tube number	1	2
3 per cent rbc suspension (prepared from the 6 per cent suspension)	1 vol.	1 vol.
Ambo. dil., 1 in 1,000	1 vol.	Nil
Saline	1 vol.	2 vol.

Tubes shaken and left in the incubator at 37°C. for $\frac{1}{2}$ hour, at room temperature 5 minutes and in the cold for $\frac{1}{2}$ hour.

Complement dil., 1 in 10	..	1 vol.	1 vol.
Tubes shaken and left in the incubator at 37°C. for $\frac{1}{2}$ hour.			

The volume conveniently may be 0.25 c.c. Any other volume kept constant will do equally well.

The result should be :—

Tube 1	Tube 2
Hæmolysis complete or partial, — or ± respectively.	No hæmolysis, +

If the amboceptor is up to the standard the hæmolysis should be complete. The tube should be crystal clear and ruby red.

Tube 2 will show that the rbc themselves are in order and unaffected by any other agent. They sink down as a red and opaque column surmounted by a clear and colourless column.

If the amboceptor of the sample is effective in a 1 in 1,000 dilution, the rabbit is bled from the heart 10 days after the last injection and about 10 c.c. of blood are collected.

If the amboceptor is not effective in a 1 in 1,000 dilution, the rabbit is given another course of rbc suspension, beginning on the same day, and the test repeated.

(When another course of injections is started only 4 days after the last injection, anaphylaxis does not occur. If there is a delay of over a week between the courses, the first injection of the subsequent course is given intraperitoneally. Following this plan the same rabbits are used for producing amboceptor again and again, without any mishap to the animals or deterioration in the amboceptor.)

Minimal hæmolytic dose, M.H.D., of hæmolytic amboceptor.—Of a satisfactory amboceptor the lowest limit of action is determined by titration. Eleven dilutions are made (in $5 \times \frac{1}{8}$ tubes) as follows :—

- (1) 0.5 c.c. ambo. + 4.5 c.c. saline = 1 in 10
- (2) 0.1 c.c. (1) + 9.9 c.c. saline = 1 in 1,000
- (3) 1 c.c. (2) + 1 c.c. saline = 1 in 2,000
- (4) 1 c.c. (2) + 2 c.c. saline = 1 in 3,000
- (5) 1 c.c. (2) + 3 c.c. saline = 1 in 4,000
- (6) 1 c.c. (2) + 4 c.c. saline = 1 in 5,000
- (7) 1 c.c. (2) + 5 c.c. saline = 1 in 6,000
- (8) 1 c.c. (2) + 6 c.c. saline = 1 in 7,000
- (9) 1 c.c. (2) + 7 c.c. saline = 1 in 8,000
- (10) 1 c.c. (2) + 8 c.c. saline = 1 in 9,000
- (11) 1 c.c. (2) + 9 c.c. saline = 1 in 10,000

The first dilution is made with saline containing 0.3 per cent trikresol and can be preserved for use indefinitely in the cold.

For dilutions (4) to (11) smaller quantities in the same proportion can be mixed. In the series given there is an automatic visual check provided by a graded increase in volume.

The dilution 1 in 1,000 is put up in two tubes again like the ear vein sample. (This step may be omitted when the complement and the rbc are being used in the routine of the laboratory and tested in the usual controls.) The dilutions 1 in 1,000 to 1 in 10,000 are put up like the first tube of this test, as shown in the TABLE OF TITRATION OF HÆMOLYTIC AMBOCEPTOR.

The last ruby red and crystal clear tube gives the titre of the amboceptor. If the 5th tube, for instance, is such a tube, the titre is 1 in 5,000. The titre is the MHD.

It will be observed that the dose is a dilution, unlike the dose of posology which is a quantity. The reason is that as the volume is kept constant the variation in the dose can only be effected by varying the dilution. The dilution therefore is the dose.

It will be also observed that the titre is given by the initial dilution unlike the titre of an agglutinating series in bacteriology, which is given by the ultimate dilution.

An amboceptor the MHD of which is below 1 in 1,000 will, of course, be rejected and not titrated at all. The one MHD of which is above 1 in 10,000 will also be rejected. When the tubes are in the incubator for the final result, they are examined after 15 minutes, 25 minutes and 30 minutes to watch the progress of hæmolysis. It should start at the left and proceed orderly towards the right. If the last tube is nearly completely hæmolysed after 15 minutes only and completely hæmolysed after

A TABLE OF TITRATION OF HÆMOLYTIC
AMBOCEPTOR

Tube No. :—	1	2	3	4	5	6	7	8	9	10
1 vol. of ambo. in a dilution of 1 in :—	1,000	2,000	3,000	4,000	5,000	6,000	7,000	8,000	9,000	10,000
Sheep rbc 3 per cent :—	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.
Saline :—	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.
Tubes shaken and left in the incubator at 37°C. for $\frac{1}{2}$ hour, at room temperature for 5 minutes and in the cold $\frac{1}{2}$ hour.										
Complement dilution 1 in 10 :—	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.
Tubes shaken and left in the incubator at 37°C. for $\frac{1}{2}$ hour.										

25 minutes, it must be presumed that the titre goes beyond 1 in 10,000.

It will be observed that the MHD of the amboceptor is determined in an excess of complement.

The usual sensitized rbc suspension used in complement-fixation.—It consists of 3 per cent rbc sensitized with 5 MHD of amboceptor and is prepared thus :—

—If the MHD is 1 in 5,000, a dilution 10 times as strong is prepared, i.e., 1 in 500. It has in a volume 10 MHD.

—A volume of this dilution is mixed with an equal volume of 6 per cent rbc.

The result is 3 per cent rbc sensitized with 5 MHD of amboceptor. The mixture is incubated at 37°C. for $\frac{1}{2}$ hour and left in the cold $\frac{1}{2}$ hour.

The Complement

The collection of this reagent has already been described.

Minimal hæmolytic dose, MHD, of complement.—Dilutions are made (in $5 \times \frac{5}{8}$ tubes) as follows :—

(1) 0.5 c.c. complement + 4.5 c.c. saline	= 1 in 10
(2) 1 c.c. (1) + 1 c.c. saline	= 1 in 20
(3) 0.7 c.c. (1) + 1.4 c.c. saline	= 1 in 30
(4) 0.5 c.c. (1) + 1.5 c.c. saline	= 1 in 40
(5) 0.4 c.c. (1) + 1.6 c.c. saline	= 1 in 50
(6) 0.4 c.c. (1) + 2 c.c. saline	= 1 in 60
(7) 0.3 c.c. (1) + 1.8 c.c. saline	= 1 in 70
(8) 0.3 c.c. (1) + 2.1 c.c. saline	= 1 in 80
(9) 0.3 c.c. (1) + 2.4 c.c. saline	= 1 in 90

The quantities of the 1 in 10 dilution and saline are written down on the tubes with glass marking pencil. The tubes are charged separately with individual quantities picked up in the pipette. *Calculation on the stem of the pipette must never be attempted.*

These dilutions are put up with a constant volume of 3 per cent rbc sensitized with 5 MHD of amboceptor as shown in the TABLE OF TITRATION OF COMPLEMENT.

The tube without the complement should not be affected.

The last crystal clear and ruby tube gives the titre of the complement. If the 5th tube, for instance, is such a tube, the titre is 1 in 60.

The titre is the MHD.

Usually it is not necessary to go beyond the 8th tube, i.e., 1 in 90 tube.

A complement not active in a 1 in 20 dilution is discarded. A highly coloured pink or brown complement which is likely to impart a tinge to the total fluid, in its *ultimate* dilution, is also discarded. The ultimate dilution will, of course, depend on the titre. Thus, while a coloured complement of high titre may be used the one of a low titre must be rejected.

It will be observed that the MHD of the complement is determined in an excess of amboceptor.

The complement completes the action between the rbc and the hæmolytic amboceptor.

A TABLE OF TITRATION OF COMPLEMENT

Tube No. :—	1	2	3	4	5	6	7	8	9	10
1 vol. (0.25 c.c.) of complement, diluted 1 in :—	20	30	40	50	60	70	80	90	100	No comp.
Saline :—	2 vol.	2 vol.	2 vol.	2 vol.	2 vol.	2 vol.	2 vol.	2 vol.	2 vol.	3 vol.
3 per cent rbc sensitized with 5 MHD amboceptor :—	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.	1 vol.

Incubated at 37°C. for $\frac{1}{2}$ hour.

Further, 1 MHD of complement will hæmolyse 1 volume of the 3 per cent suspension of rbc sensitized with 5 MHD. Less than 1 MHD will fail to do so: Herein lies the constant measure of the complement.

THE PRINCIPLE OF COMPLEMENT-FIXATION

Two systems depend upon the same restricted quantity of complement for the completion of their action. The first system is the supposed antigen-antibody system, such as the Wassermann antigen and the serum of a patient suspected to be suffering from syphilis. The complement is first presented, in a tube, to such a combination and the tube incubated. Later, the sensitized rbc are added to the same tube and the tube incubated again.

Three results are obtained:—

1. The rbc remain unaffected (+) = no complement available for them in the tube = complement-fixation by the 1st system = antigen-antibody relationship between the WR antigen and the patient's serum = WR positive = presumption of syphilis.

2. The rbc are hæmolyzed (—) = complement available for them = no complement fixed by the 1st system = no antigen-antibody relationship between the WR antigen and the patient's serum = no complement-fixation by the 1st system = WR negative = no presumption of syphilis.

3. The rbc are only partly hæmolyzed (T, trace of hæmolysis; ± appreciable hæmolysis) = only partial fixation of complement by the 1st system = WR doubtful = presumption of syphilis based on history alone. On doubtful reactions more will be said later.

(To be continued)

A TYPICAL CASE OF ISO-IMMUNIZATION AGAINST THE RHESUS FACTOR

By K. S. RANGANATHAN, M.R.C.S., L.R.C.P.

Officer on Special Duty (Blood Transfusion), Office of the Director-General, Indian Medical Service, New Delhi

CASES of congenital hæmolytic disease (Erythroblastosis foetalis) and hæmolytic transfusion reactions due to iso-immunization against the Rhesus factor have not been reported in India. Greval *et al.* (1946) reported an unsuccessful search for cases of Erythroblastosis foetalis in the maternity hospitals of Calcutta. Khanolkar and Sanghvi (1945) did not find a single case among 3,000 consecutive labour cases admitted to the Nowrosjee Wadia Maternity Hospital, Bombay. Enquiries by the writer in Madras and other centres throughout India in the course of his tours have been equally unsuccessful.

Studies to date on the incidence of the Rh factor in the Indian population have shown that the frequency of Rh negative individuals is lower in India than in European countries and

America. Greval and Roy Chowdhury (1943) found it to be 10 per cent in Calcutta, Khanolkar and Sanghvi (1945) 2 per cent in Bombay while Ranganathan *et al.* (1946) found it to be 4.1 per cent in Madras. Wiener (1945) has recorded an incidence of 7.1 per cent among 156 Asiatic Indians tested by him in New York. The incidence of Rh negative individuals is therefore not so low in India as to account for the extreme rarity of cases of Erythroblastosis foetalis and hæmolytic reactions due to iso-immunization against the Rhesus factor. It is now known that not only a Rh negative, but even a Rh positive person may be sensitized and a person of one Rh subgroup can form antibodies against the antigen of another subgroup. Further the larger number of children born in each family in India may be expected to result in a larger number of affected children. It would therefore appear that cases of hæmolytic disease of newborn have hitherto escaped recognition for want of proper laboratory investigation as in the case reported below.

Greval *et al.* (1946) have recently recorded a presumptive case of Erythroblastosis foetalis due to Rh incompatibility. Investigation of a patient recently referred to the writer by Dr. G. N. Bahadur of New Delhi has revealed such conclusive evidence of iso-immunization of the mother against the Rh factor that it is considered of sufficient clinical interest for publication.

Past history.—Mrs. P. R., aged 26 years, has been married seven years and been pregnant seven times. No history of previous blood transfusion.

First and second pregnancies terminated in abortion about the 3rd month in December 1939 and August 1940 respectively.

Third pregnancy went on to full term after a threatened abortion in the 3rd month and a healthy female baby was born on 26th October, 1941. The child is now 5 years and well.

Fourth pregnancy ended in an abortion in the 3rd month in August 1942.

Fifth pregnancy. A male baby was born on 17th November, 1943. It remained well on the first day but became 'pale' on the 2nd day and died on the 3rd day after birth.

Sixth pregnancy. A normal male child was born on 20th February, 1945. On the 2nd day after birth the child was noticed to become yellowish which the doctor diagnosed as jaundice. The baby was given an injection (presumably intramuscular) of mother's blood. The baby died on the 4th day.

Seventh pregnancy. A healthy looking male baby was born on the 25th August, 1946. Jaundice developed on the 2nd day and rapidly became severe. The baby died on the 4th day.

The mother's blood was tested in March 1945 and found to be doubtful to Kahn test. She was treated by a course of 12 injections. Subsequent blood tests are reported to have been negative.

Investigation.—Neither anti-Rh serum nor known Rh negative and Rh positive cells were available and evidence for the presence of 'atypical antibodies' in the mother's blood had to be looked for without the use of these reagents. Fortunately there are now *in vitro* tests for Rh sensitization which do not require anti-Rh sera for performing them.

It is proposed to review the tests briefly in order that when suspected cases are encountered in future preliminary investigations on similar lines may be carried out. The tests are:—

1. The Diamond-Abelson test (Diamond and Abelson, 1945).

2. Wiener's conglutination test (Wiener, 1945a).

3. Chown's capillary tube test (Chown, 1944).

Diamond-Abelson test.—This is a simple and rapid slide test. Approximately 0.2 c.c. each of fresh oxalated group O, Rh negative and group O, Rh positive cells of different specificities are placed on a slide, and to each is added 0.1 c.c. of the serum to be tested. The slide is gently rotated and repeatedly tilted. The reaction is accelerated by warming the slide to 37°C. but the test is easily performed at room temperature. The reaction is read on a ground glass or white surface. If the serum is from a sensitized person, agglutination visible to the naked eye appears in one to three minutes. In practice, it is not necessary to measure out the serum or cells accurately. One drop of blood from the finger is mixed with about an equal amount of serum. Nor is it necessary to be particularly concerned about the specificity of the red cells used if the test is set up with several different specimens of Rh positive blood. The infant's or father's red cells, if of the same blood group as that of the mother, may be used as the test cells. The mother's cells may be conveniently employed as the Rh negative control. The chief source of error in interpretation is due to rouleaux formation. A drop of saline solution added to the mixture with restirring and agitation reveals the difference between true agglutination and rouleaux formation.

The conglutination test.—It differs from the tube 'agglutination test' in the substitution of normal compatible human plasma or serum in place of normal saline solution as a diluent. Thus the 2 per cent cell suspension is made up in plasma or serum instead of in saline solution. Similarly when the titration technique is followed, the serum to be tested is diluted with plasma or serum. The test is performed as follows: Two drops of a 2 per cent suspension of group O, Rh positive cells in compatible plasma or serum are placed in a small test tube. Two drops of the serum to be tested are added. After shaking the tube is placed in a water bath at 37°C. for one hour. The appearance of the cell deposit is noted. A smooth outline is characteristic of the negative result. In positive cases the outline is irregular and

crenated in appearance. The tube is very gently shaken and agglutination looked for with the naked eye or with the aid of a hand lens. If there is no clumping, one drop of the mixture is examined under the microscope for confirmation of the absence of agglutination. The result is controlled by testing with a Rh negative blood.

The capillary tube test.—It is a very simple and rapid test requiring a minimum of equipment and reagents. Capillary tubes of 0.4 mm. bore and 8 cm. in length are sterilized in a test tube. One end of the capillary tube is dipped into the serum to be tested and a column about 2 cm. in height is allowed to run in. The tube is next dipped into fresh group O, oxalated or citrated blood and an equal column of blood drawn in, care being taken to prevent air bubbles getting in between the serum and blood. The tube is tilted up and down 2 or 3 times to mix the blood and serum. The blood end is then inserted into a plasticine rack at an angle of 45° to the horizontal, but the flatter the better. After incubation for 15 minutes at 37°C. the result is read against a white background. If positive, a beaded layer of cells is formed along the lower side of the capillary tube. A negative test, on the other hand, forms a long, thin smooth line.

Samples of blood from the father, five-year-old child, the mother and her seventeen-year-old brother were collected in dry sterile tubes and in oxalate. They were grouped according to the ABO system. The father's blood belonged to group B, while that of the others belonged to group O.

Tests for Rh sensitization

(a) *Diamond-Abelson test.*—In the absence of known Rh positive cells the sensitivity of the mother's serum was tested against twelve different bloods of group O chosen at random (including that of the child and the brother) under the presumption that most, if not all of them, would be Rh positive. For the negative control, the mother's own cells were employed. The mother's serum agglutinated 11 out of 12 group O cells it was tested against, the brother's blood alone being negative.

(b) For the conglutination test the writer's serum (group AB) was used as the diluent. The test was positive with all the 11 bloods which were found positive by the Diamond-Abelson test. Thus there was complete parallelism between the two tests.

The capillary tube test was not performed. Table I shows the results of tests for Rh sensitization.

The two tests thus revealed that the mother (group O) possessed in her serum an 'atypical agglutinin' capable of agglutinating most other bloods of group O. That it was not a 'cold' or 'auto-agglutinin' was shown by the failure of the serum to agglutinate its own cells and those of the brother. The titre of the antibody was next ascertained by titration against cells of

group O from two different persons (nos. 1 and 2) whose cells had been previously found to be sensitive to the serum. Saline solution was used as the diluent. The titre of the antibody in each case was 32.

It now remained to identify the nature of the sensitizing antigen. A supply of anti-Rh₀ serum was luckily available from the King Institute of Preventive Medicine, Guindy, Madras, and from the Army Transfusion Centre, Poona. Parallel tests were put up using the two different anti-sera and identical results were obtained. The father and child were Rh positive while the mother and her brother were Rh negative. All the other group O test cells were Rh positive. The antibody in the mother's serum reacted specifically against Rh positive cells and was therefore anti-Rh antibody. Further investigation to determine the specificity of the mother's serum is in progress.

Discussion

It is generally believed that anti-Rh serum is indispensable for investigation of suspected cases of Erythroblastosis foetalis. The fact that the mother is Rh negative while the father and child are Rh positive could be a mere coincidence. It is, on the other hand, more important to demonstrate the presence of the immune antibody in the mother's blood and its specificity to the child's cells. Anti-Rh sera are, however, necessary for determining the nature of the sensitizing antigen. With the help of the tests reviewed above it is possible for the clinician not only to make a presumptive diagnosis of iso-immunization, but he can apply the same tests as compatibility tests for selecting compatible donor for transfusion of the mother or infant. In the present case, it will be seen that the brother's blood alone is compatible. The tests

are very simple and can be performed in any well-equipped hospital laboratory.

The case reported is a typical one of iso-immunization against the Rh factor and satisfies all the criteria necessary for a diagnosis, *viz*, Rh hetero-specificity of mother and child and the presence in the mother's serum of immune agglutinins specific for the child's cells. It may be questioned how the first child, though Rh positive, escaped being affected by Erythroblastosis. It is well known that the first child generally escapes the affection as the mother is not sufficiently sensitized during the first pregnancy to cause the disease in the child. Though the first living child in this family was born of the third pregnancy, the first two pregnancies had each ended in abortion in the third month and had therefore not advanced far enough to bring about sufficient sensitization of the mother. It follows that the cause of the first two abortions and even of the third must be due to some other factor.

As regards the prognosis of future births, it may be predicted that all the children would probably be Rh positive and so develop the disease in an increasingly severe form. The reasons are: (1) the first child is Rh positive and the last three babies, born apparently well, each developed what looks like Erythroblastosis foetalis and died of it within a few days. They must therefore have all been Rh positive. (2) The father is probably of the genotype RhRh (homozygous) and so all future babies would be Rh positive. (3) Four months after the birth of the last baby the mother's serum contains immune Rh antibodies in a fairly high titre and future pregnancies will result in further immunization with increase in the concentration of the antibodies in her blood. It may, however, be possible to save the baby by timely blood transfusions with group O, Rh negative blood.

Summary

1. A typical case of iso-immunization against the Rh factor—apparently rare in India—is recorded.

2. Tests for Rh sensitization not involving the use of anti-Rh serum are reviewed and suggested for preliminary investigation.

3. It is suggested that congenital hæmolytic disease (Erythroblastosis foetalis) is probably not so rare in India as it is supposed to be.

My thanks are due to Major M. H. Shah, I.M.S., Superintendent, Irwin Hospital, New Delhi, for kindly affording facilities for investigation in the hospital laboratory and to Dr. Sher Singh, Pathologist to the Hospital, for valuable co-operation and providing test bloods. I am specially indebted to Dr. C. G. Pandit, D.B.E., Director, King Institute of Preventive Medicine, Guindy, Madras, and to Major G. W. G. Bird, I.M.S./I.A.M.C., Officer Commanding, Army Transfusion Centre, Poona, for the supply of anti-Rh₀ serum.

My grateful thanks are due to Lieut.-General R. Hay, C.I.E., I.M.S., Director-General, Indian Medical Service, New Delhi, for permission to publish this article.

A Mirror of Hospital Practice

CEREBRAL MALARIA IN PREGNANCY SIMULATING ACUTE YELLOW ATROPHY OF THE LIVER

By D. PARANJOTHY, M.B., B.S., D.G.O. (Mad.),
D.T.M. (Cal.)

Christian Hospital, Azamgarh

A HINDU patient, age 40 years, 8th para, was admitted on 4th September, 1946, at 6 a.m., with a history of 8 months' amenorrhœa, vomiting, headache, labour pains and draining for the past 5 days.

History of previous deliveries.—All full term—natural. The first child died at 2 months—the rest are alive. Date of birth of last child 2 years ago.

Condition on admission.—Patient deeply jaundiced, drowsy and restless. Puffiness of hands, face and feet. Rash pale pink, fine and slightly raised on face and neck. Pupils normal—reaction sluggish—no photophobia. No hæmorrhages. Tongue coated, dry, tremulous and deep yellow. Abdomen—liver $1\frac{1}{2}$ inches and spleen 1 inch below costal margin. Circulating system—heart normal—pulse 98, volume fair. Blood pressure 90/60. Temperature normal. Respiratory system—dyspnoea—stertorous breathing. Urine—diminished in quantity, reaction acid, specific gravity 1.020, highly coloured, albumen 2 plus, sugar 1 plus, bile salts and pigments 2 plus. Numerous casts, granular casts predominating, red cells 3 plus, tyrosin crystals present. Height of uterus—32 weeks, not acting. Position of foetus—R.O.A. Fœtal heart not audible. Relation of head to pelvis—floating. Vaginal examination—Os $2\frac{1}{5}$ ths dilated. Cervix soft. Presenting part high up. Membranes bulging. Offensive discharge present.

Patient vomited a round worm soon after admission.

Treatment.—Soap and water enema given with good result—deep yellow motion.

11 a.m. Membranes artificially ruptured. 20 c.c. of $12\frac{1}{2}$ per cent glucose given intravenously. Glucose and sodium bicarbonate given by mouth frequently.

2 p.m. Pains commenced.

3.15 p.m. Birth of a dead female child which was also jaundiced.

3.30 p.m. Placenta expressed—placenta and membranes entire. Patient continued to be restless.

10 p.m. Patient became boisterous. Morphia gr. $\frac{1}{4}$ given.

5th September, 1946. Patient slept fairly well during the night. Passed a motion in bed—deep yellow in colour and very offensive. Patient comatose, and restless again.

12 midday. Pulse 140, feeble. Temperature (rectal) 106°F .

2 p.m. Patient expired.

Pathological Findings

Liver.—The general structure of the liver has been preserved. Liver cells show no evidence of cloudy swelling or degeneration, and the nuclei are well preserved. The sinusoids are dilated somewhat but are not congested. The Kupffer's cells contain small dark granules suggestive of a malarial infection.

Kidney: Macroscopic.—Capsule stripped easily, leaving a smooth congested surface. Demarcation between cortex and medulla good.

Microscopically the kidney shows widespread congestion and masses of the same dark pigment seen in the liver. This pigment is present in the mononuclears of the blood stream, in the glomeruli and between the tubules. The pigment resembles that seen in malaria.

Comment

The pathological findings suggest malarial infection, but at the time of admission diagnosis was difficult because of—

(a) Inability to obtain a correct history of the present illness—such as the exact onset of the illness, early signs and symptoms, frequency and nature of vomiting, presence of epigastric pain, giddiness, and mental disturbances. The relatives were unable to give any information concerning the patient's illness, and the patient was too ill to give further information concerning herself.

(b) Lack of information concerning previous malarial infection, or any other illnesses.

As this district is not an endemic area for malaria, malaria was not suspected.

Because of the serious condition of the patient on admission, the short duration of the illness, intense jaundice and the urinary findings, acute, yellow atrophy was suspected.

This case shows that cerebral malaria can simulate one of the toxæmias of pregnancy, and that a routine examination of blood smear for

malarial parasites and differential count is highly desirable in every pregnant woman in the tropics.

TOXIC SYMPTOMS ASSOCIATED WITH QUINACRINE TREATMENT

By D. K. NANDI, L.M.P.

Toxic symptoms such as restlessness, staring at others, incoherent talks, shouting all day and night, etc., were observed in 16 cases of malaria patients out of 450 treated with quinacrine. The average dose in all the cases did not exceed 2.8 gm. in one course of treatment. Majority of the cases referred above developed symptoms on the 3rd to 4th day of quinacrine administration. The aetiological factors responsible for such symptoms may be due to either individual susceptibility to the drug or specific toxic effect on brain tissue. Intravenous administration was not taken up in a single case as there was no such arrangement in the clinic. Large quantities of water were administered after each dose of quinacrine and the patients were allowed to go to their respective homes with advice to take more fluids whenever possible.

Treatment consisted of administration of hypnotics and large doses of vitamin B-complex (T.C.F.) orally and intramuscularly where oral administration was not possible. Large quantities of fluids also were administered for elimination of the drug from the system. In all the 16 cases mentioned, toxic symptoms disappeared in 3 to 5 days' time.

Comment.—Administration of vitamin B-complex in course of quinacrine or mepacrine treatment of malaria will probably lessen the occurrence of toxic symptoms.

A CASE OF RENAL GLYCOSURIA ASSOCIATED WITH HYPOVITAMINOSIS C.

By SACHCHIDANANDA BANERJEE, M.B.,
D.Sc. (Cal.), M.A.D.A. (U.S.A.)

Dr. A. Mitra Research Scholar in Diabetes, School of Tropical Medicine, Calcutta

This type of cases is not very common and an error in diagnosis might expose the patient to unnecessary and even harmful treatments.

A 38-year-old Bengalee Mohammedan male, a tailor, was admitted into the Carmichael Hospital for Tropical Diseases on 16th January, 1947, for the following complaints: (1) weakness, (2) frequency of micturition and (3) passage of sugar in urine. Duration of all the complaints was only two months.

The patient said that his father died of diabetes. Routine tests revealed only the presence of sugar in the urine and no other abnormality was found.

After admission the patient was fed a diet consisting of protein, 130 gm., fat, 90 gm., and carbohydrate, 200 gm., which gave him approximately 2,000 calories. Urine was collected for twenty-four hours. On an average the

patient passed 1,700 c.c. of urine. Urinary sugar was estimated daily. On the fourth day of his stay in the hospital he was fed 50 gm. glucose in a 50 per cent solution and the glucose tolerance test was performed. The patient excreted no sugar in his urine when he was fed glucose, showed a normal fasting blood sugar value and the glucose tolerance curve was also normal (figure 1). Although the blood sugar level did not rise above 167 mg. per 100 c.c. blood, the patient excreted sugar at the end of the test. This indicated that the patient had a low renal threshold for glucose. The patient was then fed for ten days a high carbohydrate diet consisting of protein, 90 gm., fat, 50 gm., and carbohydrate, 300 gm. This diet also furnished 2,000 calories approximately. Glucose tolerance

FIG. 1.
GLUCOSE TOLERANCE
CURVES

test was again performed and it was found to be normal (figure I). The urinary excretion of sugar which was estimated daily showed that the patient never excreted more than 5 gm. of sugar per day (figure II).

FIG II

The vitamin C nutrition of the patient was also studied by estimating the urinary excretion of the vitamin both before and after feeding the patient with a daily dose of 600 mg. of synthetic ascorbic acid (70 mg. per kilo). The

results are shown in figure III. Before ascorbic acid was fed the patient excreted on the average 5 mg. of vitamin C in 24 hours which was very low. After the ascorbic acid was fed there was no marked increase in the urinary excretion of the vitamin even three days after its administration. In normal individuals, however, a high

Fig. III.

rise in the urinary excretion of the vitamin is obtained only one day after the administration of the test dose of ascorbic acid. This indicated that the patient was suffering from hypovitaminosis C. The patient, however, did not show any sign of marked vitamin C deficiency as evidenced by bleeding gums, petechia, ecchymosis, anaemia, etc.

When the patient was discharged although he was excreting 5 gm. of glucose daily his weakness and frequency of micturition had disappeared. The complaints of the patient therefore seem to be due to hypovitaminosis C and not due to renal glycosuria because the latter condition is usually without any symptoms and is only revealed after accidental examination of the urine for sugar.

I am indebted to Messrs. The British Drug Houses Ltd., Bombay, for a free gift of ascorbic acid.

A CASE OF CRANIOCLEIDODYSOSTOSIS

By R. DWIVEDI

M.O. Machhalishahr, Jaunpur, U. P.

A MUSLIM boy of 15 years came in September 1946 for a sinus under his chin of 3 years' duration. He had a carious molar tooth in the lower row, which was responsible for the sinus. The sinus was scraped and the tooth removed. This resulted in closure of sinus within a few days.

While he was under treatment for the sinus, it was accidentally revealed that he had no fully developed clavicles and that shoulders could be apposed to each other in front.

Further examination revealed that each clavicle was imperfectly developed, consisted of

two pieces with a central one inch gap, with thin cartilage-like structure. Shoulder joints were rather prominent and narrow from side to side. Infraspinatus on each side was poorly developed with hollow infraspinous fossa. There were depressions and bosses over the skull.

The boy on the whole was of poor development, but had never suffered from rickets and all other bones were normal. He has been carrying on with his usual work of an agriculturist class to which he belongs.

This is a case of 'Cranioleidodysostosis', which is described as 'a very rare abnormality, which is hereditary and familial. The bones affected are those which are developed from membrane'.

I wish to thank Captain B. B. Das, Civil Surgeon, Jaunpur, for permission to publish the case report.

MEPACRINE PSYCHOSIS

By M. S. H. MODY, M.B., M.R.C.S., etc.

THE following description of a case, of the above condition, seen in consultation with his doctor, may prove of some interest to your readers.

K., Hindu, pleader, aged 42, developed fever on 8th November, 1946. For the first two days he was treated symptomatically, but as during these days the fever was intermittent, his doctor started him on mepacrine tablets from the evening of 10th November, 1946, the dose being 3 tablets per diem, in addition to the plain diaphoretic mixture. An injection of 6 grains of quinine was given on the 12th November, 1946 (blood was not examined for M.P.).

By evening of the 13th November, 1946, by which time he had taken 12 tablets of mepacrine, he became very talkative, excitable, and inclined to be rather noisy and boisterous. This was most unusual, as the patient was of a very quiet, reticent and calm disposition. The doctor, attributing this change in his disposition to mepacrine, discontinued the tablets, and treated him by sedatives, which quietened his boisterousness, but he continued to be very talkative, and at times was incoherent, his replies being confused and not rational.

By the 18th November, 1946, viz, five days after mepacrine was stopped, he again became very violent, boisterous and abusive, threw away all his clothes, got out of his bed, and assaulted his relatives. When forcibly kept in bed, he continued to shout, sing and talk to himself. These symptoms continued till the 20th November, when I saw him. All these days from the 13th to 20th November, 1946; he was running a low temperature between 99° and 101.5°. Clinical examination revealed no neurological lesion nor any evidence of meningitis or encephalitis, as these were by now suspected as the cause of his mental state.

Urine and blood film examinations now done proved normal. The latter showed no M.P.

I suggested an immediate injection of Dial (Ciba) and to be repeated at bedtime with a bromide and chloral hydras mixture.

The first injection made him sleep for about 5 hours, the first time in three days.

Next day he was much quiet, and he recognized people round about him, yet there remained a fair degree of confusion and disorientation in his ideas and talk, which gradually cleared up.

From then onwards he improved and made an uneventful recovery.

Summary

In a case mental confusion and euphoria commenced after 12 tablets of mepacrine, viz, on the fourth day after commencing to take them, gradually progressing into a violent maniacal condition although mepacrine was discontinued. This acute psychosis was at its worst on the eleventh day after taking mepacrine and seven days after the drug was discontinued.

The case must be regarded as one of mepacrine psychosis.

A CASE OF PRIMARY PNEUMONIC PLAGUE

By THAN AUNG, M.B., B.S. (Rangoon), T.D.D. (Wales)

A BURMESE female, age 28, was admitted into the isolation ward of the Civil Affairs Service Hospital, Nyaunglebin, on the morning of 16th January, 1946, suffering from fever and a slight cough of 5 days' duration. Her husband had died three days previously after suffering from fever for 7 days. There was a suspicion that her husband had died of a respiratory infection as he was alleged to have expectorated blood-stained sputum during the course of his illness. He was not admitted into hospital. On admission she had no apparent dyspnoea or cyanosis, and had walked into hospital. There was no toxæmia, the only symptoms that she complained of were a slight cough, and a feeling of tightness in the chest.

Clinical examination.—Eyes—bright, no congestion. Tongue—betel-stained. Heart—first sound partially replaced by a soft mitral systolic bruit. Lungs—no dullness on percussion. Right base full of crepitations. Sputum—rusty. Spleen—soft and palpable. Liver—not palpable.

Laboratory examinations.—Blood—no malarial parasites seen. Total W.B.Cs. 12,200 per c.mm. with polymorphs. 83 per cent and lymphocytes 17 per cent. Sputum—character rusty. The specimen was sent to a M. F. T. U. at Pegu, 50 miles away. Report—*Pasteurella pestis* present. No culture or guinea-pig inoculation was done.

Treatment.—Before waiting for the laboratory diagnosis the patient was put immediately on admission on the following treatment:—

1. Sulphathiazole 4 tablets *statim*, 4 tablets next dose, and 3 tablets 4 hourly thereafter.
2. Leptazole, 1 ampoule 4 hourly.
3. An alkaline mixture with grs. 60 each of sodium bicarbonate and citrate, and m 20 of liq. ammon. aromaticus per ounce 4 hourly.
4. Fluids *ad lib*.

The patient's temperature began to come down within 24 hours reaching normal 48 hours after admission, and thereafter assumed an irregular curve for a further 13 days. There was continuous improvement of the patient's general condition despite the temperature. Sulphathiazole was continued for 9 days. A total dose of 63½ gm. was given. A check up white cell count was made. Total W.B.C. count was 9,500 per c.mm. Differential count: polymorphs 65 per cent, lymphos. 30 per cent, eosinos. 3 per cent, myelocytes 2 per cent. During the course of the treatment, on 20th January, 1946, the patient's output of urine became reduced, and 2 pints of glucose saline were given intravenously by the drip method. There were no further complaints. The sulphathiazole was stopped as the total dose already given was rather excessive, and there was a suspicion that the continued temperature may have been caused by the drug. Treatment was then switched on to penicillin, 10,000 units intramuscularly every three hours, a total of 360,000 units being given. The temperature then came down gradually till it reached normal 13 days after admission.

A small blood transfusion (200 c.c.) was given on 28th January, 1946. Except for suppression of urine 12 hours after the transfusion which responded to an injection of ½ c.c. of adrenalin, there was no other untoward reaction.

Physical signs in the chest as indicated by a daily examination of the right base began to disappear with the sulphathiazole therapy. This improvement however was not sustained for with the return of the temperature the crepitations returned, and persisted till 5th February, 1946, when no physical signs could be detected.

Sputum.—After the diagnosis was established, the sputum was not examined till 2nd February, 1946, onwards when a daily direct smear revealed cocco-bacilli with bi-polar staining, till 5th March, 1946, when no such organisms were detected. The patient was discharged when 3 negative results were obtained. An attempt was made to determine whether the cocco-bacilli seen through the microscope was *Pasteurella pestis* or a normal inhabitant of the upper respiratory passages, as the stain used was a 1 to 10 dilution of carbol-fuchsin, and differentiation was rather difficult. Unfortunately the specimen sent for culture and if necessary animal inoculation did not reach the laboratory which was in Rangoon 100 miles away.

The unusual features of this case are:—

1. The absence of any toxicity throughout the entire illness, in spite of the fact that the

condition is notoriously dangerous, and death usually occurs within a few days of the onset. The patient came into hospital on the 5th day of her illness, and on a cursory examination there was nothing to suggest that it was a case of pneumonic plague.

2. The low grade of infectivity in this case when this condition is one of the most infectious of all acute contagious fevers. The two relatives of hers, apart from being inoculated with Haffkine's anti-plague vaccine, did not observe even the most elementary precautions while they were nursing her. Both of them are still alive and well.

3. The large amount of sulphathiazole that was administered with little or no toxic symptoms, except a slight diminution in the urinary output, which responded to intravenous glucose saline, a total dose of 63½ gm. being given spread out over 9 days.

4. The record of her temperature revealed a secondary rise which continued for 4 days after the drug was stopped, and 4 days after the institution of penicillin therapy. Whether the temperature was due to the sulpha drug, the so-called 'drug fever', or whether penicillin exerted its effect on the infection I cannot say, but the patient's temperature remained normal till her discharge.

5. The blood transfusion was given on the rationale that a fresh supply of leucocytes would help in overcoming the infection.

6. The presence of cocco-bacillary organisms in the sputum long after she had clinically recovered from the infection makes the condition rather interesting. Unfortunately, it was impossible to determine whether the organisms seen were *Pasteurella pestis* or not. Their persistence in the sputum, if they were really plague bacilli, in conjunction with the fact that pneumonic plague is a rarity in Burma where bubonic plague is endemic, and that explosive outbreaks of primary pneumonic plague occur, claiming a number of victims and then subsiding would appear to suggest a carrier condition as in cerebro-spinal fever.

Therapeutic Notes

NOTES ON SOME REMEDIES

IX. AMŒBICIDES

II

By R. N. CHAUDHURI, M.B. (Cal.), M.R.C.P. (Edin.),
T.D.D. (Wales), F.S.M.F.

Professor of Tropical Medicine, School of Tropical
Medicine, Calcutta

General principles of treatment

THERE is still an impression that the treatment of intestinal amœbiasis consists in simply giving a course of emetine injections which can be repeated periodically if the symptoms persist. This probably arose from the fact that,

as with all new methods of treatment, early reports on emetine were unduly optimistic. The immediate effects of injections on the acute stage of amœbic dysentery, with active forms of *E. histolytica* in the faeces, are undoubtedly dramatic, but clinical cure and permanent freedom from infection are by no means always synonymous. As long ago as 1917, Dobell found that full courses of emetine hydrochloride given hypodermically were successful in about a third of the cases treated (nowadays perhaps this would be put at a still lower figure), but unfortunately his pioneer work seems to have escaped the notice of many clinicians. So unless the patient's resistance is very good, emetine needs supplementing with other drugs. To go on giving it when it fails initially is not only useless but hinders subsequent radical treatment.

In considering the therapeutic problem it is necessary to remember that the active vegetative amœbæ after gaining entrance in the tissues of the large bowel multiply and form small abscesses in the submucosa which burst and become ulcers. These ulcers extend peripherally and deep into the submucosa. After a time some of the amœbæ pass into the lumen of the bowel and assume cystic forms after passing through a precystic stage. These precystic and cystic forms are not found in the tissues but congregate on the mucous surface of the bowel where they lie embedded in the mucus. The mature cysts eventually leave the body with the faeces, but the important point is that emetine given hypodermically has not much chance to act on the amœbæ and cysts lying within the bowel. To extirpate them the drug must be introduced directly into the alimentary tract, and emetine-bismuth-iodide was the first drug elaborated to achieve this local action. But even oral medication is not always enough. Amœbic ulcers may be scattered about anywhere between the cæcum and rectum, and those situated lower down in the canal are not so well acted upon by drugs given by the mouth. Hence it has been long customary to give rectal injection of eusol or silver nitrate solution especially in chronic cases in which the rectum and the sigmoid are invariably involved, but chiniofon is the best for this purpose.

There is another important factor which often militates against radical cure and that is the secondary infection of the ulcers with pyogenic organisms. Nearly 20 years ago Acton and Knowles (1928) stressed the importance of streptococci in resistant cases and commented that the whole bacterial flora appeared quite changed from the normal. This secondary infection together with the fibrotic changes in the ulcers may well prevent emetine from exerting its effect on the *E. histolytica*. Indeed there are clinicians who attribute the so-called emetine-resistance to this cause only, and it is highly probable that many of the toxic and emaciated cases are not so much due to the

virulence of the amoebae as to the widespread secondary bowel infection. In several chronic resistant cases preliminary treatment with penicillin and sulphasuxidine has been given with very encouraging results; it has made them more amenable to treatment with drugs which have a specific action on the amoebae.

The position, therefore, is that no single drug will eradicate more than a certain proportion of infections. Emetine hydrochloride is the only known satisfactory drug in the treatment of amoebic hepatitis and amoebic liver abscess. Its efficiency in amoebiasis of the intestine is limited to the control of acute symptoms, but there is too often a tendency to repeat the procedure unduly. Repeated experiences have shown that the vast majority of cases are thereby rendered less amenable to treatment with other available drugs. Of these the most commonly used are emetine-bismuth-iodide, carbarsone, vioform and diodoquin by mouth and chiniofon by rectum. The usual procedure is to give a combination of two or more of these drugs with or after preliminary use of emetine in an endeavour to obtain sterilization. Opinions differ as to the best combination, but the prospects of radical cure are quite good although there is room for improvement and a search for more effective remedies is very desirable.

Acute amoebic dysentery

The patient should be confined to bed and put on a suitable diet. The treatment is initiated with a course of daily injections of emetine hydrochloride in $\frac{1}{2}$ to 1 grain dose given in the way previously indicated. Along with emetine carbarsone is given by mouth in dosage of 0.25 gm. (in capsule) twice daily for 10 days. The response in the majority of primary cases is evident within 48 hours, and the diarrhoea ceases in 4 or 5 days. After two or three weeks the stools should be examined and, if possible, also the material obtained by sigmoidoscopy or proctoscopy. Cysts or the vegetative forms of *E. histolytica* seldom reappear in the faeces until 10 to 20 days after treatment and negative stools in the first 10 days are not reliable as regards eventual cure. If negative, this examination is repeated two or three times or more for the passage of amoebae in the faeces is often intermittent. Actually the above treatment does not cure the infection in a proportion of the cases, so it is advisable to give after ten days a further course of carbarsone or a course of diodoquin, 3 tablets (3.2 grains each), thrice daily for 20 days. This clears up most of them, but a few may still remain resistant to treatment though there is nearly always symptomatic improvement.

Relapses

These occur when the patient's power of resistance is poor or where treatment has been inadequate. Relapses tend to become more frequent and more resistant to treatment the longer

the infection has been present. Only a few injections of emetine are given, if necessary, to control acute symptoms but it is unlikely to do much good if the patient has already had prolonged courses. Manson-Bahr (1945) strongly recommends combined treatment with emetine-bismuth-iodide by mouth and chiniofon by rectum for 10 days, and indeed he is in favour of giving this treatment as a routine even in acute cases of dysentery after preliminary use of emetine. This was also the standard treatment in the British army during the last war. It has not become very popular in Indian civilian practice owing to its unpleasant nature, but it should not be difficult to adopt in hospitals. It is most necessary that these drugs should be used with meticulous attention to details which have already been given, otherwise the results will not be satisfactory. The treatment which can be repeated is completed with a course of carbarsone for 10 days.

Willmore (1945) claims to have obtained equally good results from the following treatment:—

On odd days: one 'slipule' of auremetine, 1 grain, three times daily to a total of 10 days.

On even days: tablet stovarsol, 0.25 gm., three times a day to a total of 7 days; chiniofon retention enema of one litre daily, the first two of 2½ per cent, the last eight of 4 per cent.

Mateer and others (1940) got 97 per cent of success by combining carbarsone with chiniofon enemas. The failures were later cured with vioform.

We need not mention similar other combinations that are preferred by different clinicians, but of late diodoquin is being increasingly used in the treatment of chronic cases. It is well tolerated in all but a small minority of cases and has sometimes caused effective and dramatic cures. In addition it has a good moral effect on patients who had previously had repeated courses of a depressing drug such as E.B.I. especially when they notice rapid clinical improvement following its use. Occasionally some of the chronic relapsing cases do not show much clinical improvement even after one or other of these standard treatments, but continue to pass stools mixed with pus, mucus and blood, probably owing to concomitant bacillary dysentery. Such cases are often benefited by a course of sulpho-namide treatment (*vide infra*).

Chronic amoebic dysentery

As a result of long continued infection by *E. histolytica* and bacteria the patient suffers persistent diarrhoea and his condition deteriorates in spite of treatment. He becomes cachectic and pyrexial with abdominal pain and tenderness, and sigmoidoscopy shows ulceration of the rectum. These cases show little or no response to standard treatment. Being impressed by the part which bacteria might play in preventing response to anti-amoebic treatment, Hargreaves (1945) has treated several such cases

successfully with penicillin and sulphasuxidine. The total dose of penicillin is about 2 million units, given in 30,000 unit doses intramuscularly every 3 hours. Concurrently a course of sulphasuxidine 20 gm. or phthalyl sulphathiazole 10 gm. daily is given for the same period. If necessary either of these drugs may be substituted by sulphaguanidine, sulphadiazine or sulphathiazole in appropriate dosage. After this preliminary course ordinary anti-amoebic drugs should be administered. The complete treatment which is summarized below is recommended for refractory cases who have ulceration which is visible with the sigmoidoscope, or clinical and radiographic evidence of localized disease such as local tenderness and thickening or induration with filling defect.

Day 1-8. Penicillin and sulphasuxidine in doses given above.

Day 9-20. E.B.I. each night and chiniofon retention enema each morning.

In lieu of E.B.I. and chiniofon enema a 20 days' course of diodoquin by mouth.

Day 21-30. Carbarsone for 10 days.

A certain number of the chronic cases pass gradually into a state of non-specific colitis, differing little from chronic bacillary dysentery or so-called ulcerative colitis. It is frequently difficult to demonstrate amœbæ in the stools. The condition is commonly accompanied by malnutrition and cachexia and sometimes associated with faulty absorption. These patients should receive hæmatinics and vitamins, especially B-complex, in addition to both anti-bacterial and anti-amoebic treatment. Medicated bowel washes (sulphaguanidine, silver nitrate, etc.) are usually necessary. The importance of general treatment must be emphasized. The chronic patients should be given as full a diet as possible, avoiding coarse vegetables, spices and alcohol. It is essential to have a cheerful atmosphere for too often they become bowel-conscious and develop anxiety symptoms.

Tests of cure

Two to three weeks after treatment is completed, three daily specimens of stools are examined and sigmoidoscopy is performed. It should be remembered that sigmoidoscopic findings may be positive when stools are negative and *vice versa*. Again after a month six further daily stools are examined and sigmoidoscopy is repeated. But such examinations are only possible under hospital conditions. An alternative is to follow up the clinical history of the patient for at least a year after treatment has been discontinued. Certain signs are valuable, though not infallible, guides to the presence of activity: mucus in the stools with or without blood, tenderness over the iliac fossa and palpable cæcum or colon.

Complications

In the absence of abscess formation, patients with hepatitis always respond quickly to

emetine. A full course should be given preferably combined with diodoquin to eradicate infection in the bowel. When abscess has formed, the recognized treatment is emetine plus aspiration repeated as considered necessary. When it is secondarily infected with bacteria, aspiration with chemotherapy appears to give far better results than open operation which has until recently been the common method of treatment in this condition, though associated with high mortality. Latterly we (Chaudhuri and Chakravarti, 1947, in press) treated successfully a case of liver abscess infected with anaerobic streptococci by repeated aspiration along with penicillin systemically as well as locally into the cavity. Aspiration was done on alternate days at first and later at intervals of several days, being guided by the rise of temperature and local tenderness, 50,000 units of penicillin being injected into the abscess cavity after each aspiration. During a period of five weeks he was aspirated ten times. Besides he was given penicillin injections, 20,000 units three hourly, for seven days. This method of treatment should be tried first before considering open drainage. *Amœbiasis of the lung* is not uncommon in this country although it is apt to remain undetected or perhaps wrongly diagnosed as pulmonary tuberculosis. Response to emetine is usually striking, but there may be aggravation of symptoms after the first few injections (Chaudhuri and Rai Chaudhuri, 1946). *Amœbic ulcers of the skin* that may follow opening of peri-rectal abscess or a colostomy wound clear up readily with emetine therapy.

Cyst-passer

Persons may pass *E. histolytica* cysts in their stools with or without previous history of amœbic dysentery. Though apparently healthy, they may develop acute intestinal symptoms or some other serious disease at any time. Though they pass cysts, the amœbæ are also present in the tissues. These cases are often satisfactorily treated with carbarsone alone or with emetine and diodoquin. Stools should be re-examined four to six weeks after treatment.

TESTS ENDORSE BOVRIL CLAIMS

Most effective gastric stimulant

For over 50 years Bovril has been regarded by the Public as a body-builder, a stimulant and a standby in all cases of weakness. This faith in Bovril was, and is, based on the finest of all proof—personal experience. But it is natural that the exact reasons for the unique powers of Bovril should have been investigated, and experiments have from time to time been carried out by the medical profession.

In 1911, the late Professor Thompson, of Dublin, established that Bovril had the power of ministering to nutrition by the assistance it gave to the assimilation of other foods. Recently a remarkable series of experiments has been conducted at an English University. A group of medical students volunteered to undergo the unpleasant experience of allowing the passage of an œsophageal tube into the stomach so that accurate studies might be made of the effect of

certain beef preparations. One of the substances investigated was Bovril.

As a result of these experiments (described in detail in the *British Medical Journal* of August 28th, 1937) Bovril emerged as 'the most effective stimulant.' Briefly, it was proved that Bovril increased the supply of gastric juices where there was a deficiency and restored it to normal. It is an accepted medical fact that people of sedentary habits generally suffer from a lowering of the essential gastric activity; Bovril rectifies this and, by facilitating the digestion of proteins, enables full nourishment to be gained.

Everyone, therefore, who is run down through strain or illness, or who feels in need of extra strength to cope with the demands of modern life, should take a cup of hot Bovril daily. It is a delicious and stimulating way of keeping fit and strong.

BOVRIL

STIMULATES DIGESTION

THE RELIEF OF DIGESTIVE DISTURBANCES

In the treatment of digestive disturbances especially where there are indications of gastritis, peptic ulcer, cholemesia and other *sequelae* of hyperacidity, Cal-Bis-Ma will provide an excellent antacid particularly useful in the treatment of these pathological conditions. This preparation has pronounced sedative action upon the inflamed mucosa of the digestive system, and provides alkaline medication in a form palatable alike to children and adults.

SOME B.D.H. MEDICAL PRODUCTS FOR USE IN GENERAL PRACTICE

ACETYLCHOLINE B.D.H.

A standard preparation for the relief of peripheral vascular disorders and other parasympathetic derangements such as paralytic ileus. Similar but more prolonged effects are produced following the use of Carbachol B.D.H.

MERSALYL B.D.H.

The most reliable diuretic for use in producing prompt and profuse diuresis, even over prolonged periods. Treatment is by injection supplemented by oral administration.

ANACARDONE

Nikethamide B.P. is an accepted cardio-respiratory stimulant, indicated in all forms of shock, surgical, obstetrical, electric and toxic (from barbiturate poisoning etc.) as well as in infective conditions and convalescence therefrom.

PROGESTIN B.D.H.

The hormone of the corpus luteum indicated for the treatment of menorrhagia, habitual and threatened abortion and certain cases of spastic dysmenorrhœa.

Stocks of B.D.H. Medical Products are held by leading chemists and full particulars are obtainable from—

HOMO SAPIENS

THE proper study of mankind is man. Striking biological features.—The species possesses many such features. The first feature is the polytypicity (Cole, 1937; Burkitt, 1946). Well-defined types fully definable in terms of anatomy and also differentiated fully or partly by blood group distribution exist and have existed presumably ever since the species made its appearance on this planet. Such types are known in domestic animals also, an example being the dog. They have been created by man through selection. In man they seem to have appeared spontaneously by mutation and then been preserved by isolation and inbreeding. Language appears to have played an important rôle in bringing about the isolation and inbreeding.

Even in the sub-Homo and sub-sapiens species the polytypicity appears to have been striking. Amongst the sub-Homo species, the Peking man (*Sinanthropus*), the Java man (*Pithecanthropus erectus*), and the Piltdown man (*Eoanthropus*) and their contemporary in India (*Sivapithecus*) are alike and yet different. Amongst the sub-sapiens species, the Neanderthal man (*Homo neanderthalensis*), the Heidelberg man (*Homo* or *Palaeoanthropus heidelbergensis*) and Rhodesian man (*Homo rhodesiensis*) are again alike and yet different. Almost so are the various types of the *Homo sapiens* to-day. The sub-Homo species have disappeared. The sub-sapiens species may have survived, more or less mixed, in the negroid and australoid races of to-day.

(It will be noticed that the Heidelberg man has been regarded both as a *Homo* and as a sub-Homo species.)

The main Primate stem of life appears to have thrown out branches which became distinct and final very soon. The old world monkeys and the new world monkeys are two other examples. Did the races of the sub-Homo man disappear because of this distinctiveness and finality? A true human type, the Bokop man of South Africa, probably the ancestor of the living Bushmen, has also disappeared. Its cranial capacity was larger than that of the modern man (1,600 c.c.). The great reptiles of the Mesozoic era which in distinctiveness and finality attained perfection and dominated the planet also became extinct. The question of undue isolation and inbreeding, caused by a language, of course, does not arise in their case.

If some day it is decided that after all most of the so-called sub-Homo species were not only *Homo* but varieties of *Homo-sapiens* then the polytypicity becomes all the more remarkable.

Such a decision is not unlikely. Only Man (i) uses fire and (ii) chews his (cooked ?) food with a rotary motion (which leaves its evidence on the mandibular joint). The species at present regarded sub-Homo did both.

On the other hand even the Neanderthal man, *Homo neanderthalensis*, might not have been so near to *Homo sapiens*. He lived in Europe for 200,000 years and disappeared after the arrival of the latter as Cro-Magnon man. He was powerful, ugly, brutish, cunning and possibly cannibalistic and incapable of articulate speech. Between him and the newcomer no love was lost. The few surviving members of Neanderthal colonies, living in caves inaccessible to the newcomers, might well have been the legendary ogres of Europe (Wells, quoting H. Johnston's *Views and Reviews*). *Fe fi fo fum* would be their speech according to the English legend. The polytypicity of to-day becomes more remarkable still.

(The Indian homologues of the ogres would be the *Rakshashas* of the semi-mythical lore. They were also powerful, ugly, brutish and cunning but not incapable of articulate speech. One family with its capital in an island controlled part of Southern India. It was overthrown by the hero of the Ramayana.)

The second feature is the striking difference in modes of living which is based on ideology which in its turn is linked with the general racial type: The spiritualistic East, the materialistic West and the cannibalistic remnants of earlier races. The first type of *Homo sapiens* appeared about 40,000 years ago, probably in South East Asia (Dale, 1946) and the Cro-Magnon man of this stock took his tribe to Europe between 40,000 and 25,000 years ago (Wells, 1931) to start the Old Stone Age. How much of the spirituality of the East is the accumulated wisdom of the older group of humanity (the elders) in the East and how much simply an escape from the depression of frustration resulting from competition with the younger group of humanity (the youngsters) in the West, may not be easy to decide. Both factors certainly exist. The cannibalistic remnants of earlier groups, probably only partly *Homo sapiens*, are an anachronism. Their day really ended when the fight with the tropical heat and wild fauna of the jungle was decided in man's favour by his inventive psychology. Some of them carry lethal genes like the gene of sickle cell anaemia, a race specific disease (Editorial, 1947).

Incidentally, the emotion allied to spirituality, the idea of unqualified devotion and unconditional surrender to the powers-that-be, is not new in zoology. The dog has the same feeling towards man, next to the dog comes the horse and next to the horse comes the elephant.

The third feature is the supremacy over the planet. The Eastern races believe and the Western races know that the Earth is their heritage. This supremacy is not new. It was

also in the possession of the reptiles in their age. No other creature has yet thrived physically so much as did the reptiles. Yet they have disappeared leaving behind a few loathsome remnants.

Man's supremacy, however, is not undisputed. Insects are very important in the tropical region, the most fertile part of the globe. Here they interfere with man much more than he can interfere with them (Allee, 1937). In their social system too the insects may be superior to man. The life of the ant is suggestive of a single vital principle common to all the members of a nest, in spite of different bodies (Maeterlinek, 1941), the *group soul* of a certain system of theology. In an emergency every ant *knows at once* what to do, without receiving any orders from any source. Human civic sense has not yet come anywhere near such perfection.

The *fourth* feature is the instability of the brain. Insanity is found in *Homo sapiens* only and has become a serious problem (Curran and Guttman, 1939). Here again probably the finality in development is the cause. Smaller upsets like hysteria are also found in the dog which again is a creature specially gifted with emotion and devotion.

Here an attractive though speculative hypothesis may be advanced: Man is unstable because he is not a mature animal really. He is an ape's foetus which has continued growth foetus-wise, assumed a respectable size and even started reproducing, neoteny. Man is a foetalized ape (Dale, *loc. cit.*). Other examples of foetalization are known in zoology: (1) Female glow worm has the structure of a beetle larva. (2) Axolotl can be turned into *Amblystoma* by injection of thyroid extract. The former although sexually mature retains the larval form of a newt in possessing gills. The latter has no gills.

The same fault in man's make-up might be held responsible for cancer in man: The essentially foetal tissue runs amok at times.

The *fifth* feature is the sense of comfort and leisure of which are born art and equity. While other animals live and move stimulated by hunger and love only, man aims at comfort and leisure also. The comfort is more than that of the body alone. While an animal elings to life at any cost a man suffering from bodily or mental discomfort often commits suicide. When he suffers acutely for reasons of sentiments he kills himself to save his honour and also sacrifices himself as a martyr or a patriot. The tales by some naturalists of scorpions committing suicide, if not discredited, show an instinct which finds full expression in man only.

Although sports are enjoyed by animals also and are the commencement of leisure in zoology, real leisure and art, like insanity, appear to be the monopoly of man only. Even the early cave dwellers decorated the walls and roofs of their caves by drawing on them pictures of life around them.

Equity appears to be the essence of human sapience. Arising from the social instincts well recognized in zoology, man's equity may be taken as a measure of human civilization and progress. It provides the only reliable evidence for judging between different races, ages and cultures of humanity.

Other measures like invention, production, comfort, art and longevity have been suggested. Yet the culture, the race or the individual excelling in fairmindedness and justice gains the leadership of the intelligentsia of the entire world, in spite of difficulties of language, time and space.

Wars and rumours of wars, and health of man.—Is war to a man what maternity is to a woman? It might have been so when it did not spread to the entire planet. But with the present trend towards perfection of lethal implements and our physicists being quite capable of blowing the planet to pieces in a day, war would be to man, what puerperal septicaemia in the pre-sulpha drug days and pre-antibiotics days was to a woman. Should the settlement of human quarrels be left to the economists (and their subservient defence services) or should social health be counted upon to create such a healthy, happy and contented world that wars and rumours of wars will not find a place in it? The latter proposition falls well within the scope of medical men. Health may supply what so far only force of arms has procured. Of health is born the joy of living; of the joy is born strength; of the strength are born the will to work, invention, production, and all necessities and amenities of life. An aggressor takes the necessities and the amenities from others by force of arms: so taken they do not last long. Nature makes the serf take his revenge. By waiting on his master hand and foot and becoming a 'yes man' he saps his virility, damages his equity and integrity, and reduces him to serfdom also, when another aggressor attacks in due course.

Besides, the messenger of health is always listened to and is able to teach what is wanted for social reform. Who should know better than a family physician the worries of a family which is the foundation of the society and of the State? It is worth knowing that all spiritual teachers of the world found their followers through miracles of healing. Let not the medical men miss opportunities. Social reform is needed in Asia generally and in India particularly.

Further, a healthy, happy and contented nation would soon teach an arrogant and aggressive neighbour that the tales of racial superiority and inferiority are myths. 'Man is a man for a' that'. In Asia he possesses his due share of mineral wealth and more than due share of earth's fertility.

Man's importance in biology.—Life on this planet would go on as usual if all men were to die overnight. On the other hand, life would not be

possible for more than a month or so if the colour bearing vegetation, responsible for photosynthesis, and the humble fungi, responsible for returning to the earth and atmosphere the dead animals and plants, were wiped out as suddenly. The photosynthesis makes food without which animals cannot live. The continuous accumulation of dead animals and plants would take up so much of land and sea that the living animals and plants would not be able to find a place anywhere. Whatever be the opinion of man on his own greatness, in the matter of large-scale protoplasmic transactions, he is like all other animals inferior to plants.

HISTORY OF KALA-AZAR IN INDIA*

By P. C. SEN GUPTA, M.B.

Officer-in-Charge, Kala-azar Research Department,
Calcutta School of Tropical Medicine

Introduction.—Kala-azar or the black fever was so named because in a large proportion of chronic cases there is a well-marked dark pigmentation of the skin. The word 'kala' may also have been used as signifying 'fatal' or 'deadly', because of the fact that the disease was fatal in almost all cases.

Early history.—Kala-azar is believed to have existed in Bengal for over a century now. Twining writing in 1835 described a condition

that he called 'endemic cachexia of the tropical countries that are subject to paludal exhalations'. The disease he described under this title was certainly kala-azar so closely does the description fit in with the classical picture of kala-azar. It was in 1824-25, that there was an outbreak in Jessore of a fever that was characterized by relapses, progressive emaciation and enlargement of the spleen and the liver and the occurrence of certain complications that are frequently seen or almost exclusively occur in kala-azar. This outbreak led to an appalling mortality and no less than 75,000 people died in the division. From Jessore this disease spread to Nadia in 1832 as well as to the 24-Parganahs. It reached the Hooghly district in 1857 and in 1862 it reached the Burdwan district from the contiguous Nadia and the Hooghly districts. The disease reached Burdwan town in 1866. The description by Dr. French, the civil surgeon of Burdwan, of this fever may even to-day be regarded as an excellent clinical description of kala-azar. He traced the course of the progress of the disease from the time of the Jessore epidemic to the time of the Burdwan epidemic of the sixties of the last century.

The disease was introduced into the Daeca district in 1862 by the crew of a country boat who came from upcountry to the inland port of Jageer on the Dhaleswari river. All these men died of a low remittent fever of long duration. The disease spread to this town and thence to the village and towns of the district. In four years the once populous town of Jageer had ceased to exist. The mortality was so great that the dead were left in their houses or thrown into the 'beels' or rivers. There was an epidemic of this disease in North Bengal in 1872. In Bihar it was known to have existed in 1882 and there it was called 'kaladukh'.

The spread of the disease to Assam followed in the wake of the British conquest and the opening up of communications by road and steamer services with Bengal. The first outbreak was reported in 1875 from the Garo hills, where the local population called it 'sarkari hemari' or the British Government disease. Rogers was of the opinion that the Garo hill epidemic was caused by the direct extension of the disease from the Rangpur outbreak of 1872, the route being the newly opened trunk roads along the Brahmaputra river. The map (map 2, after Rogers) shows the spread of the disease into Assam during the last quarter of the last century. Kala-azar caused terrific havoc in Assam during the period; of the people affected over 95 per cent died and this led to a serious decimation of the population, over 25 per cent of the population dying in some districts.

That kala-azar was prevalent in other parts of India, viz, the Madras Presidency and the United Provinces, was recognized after the discovery of the parasite in 1903 (see map 1).

Previous to the discovery of the parasite, several hypotheses were put forward by different

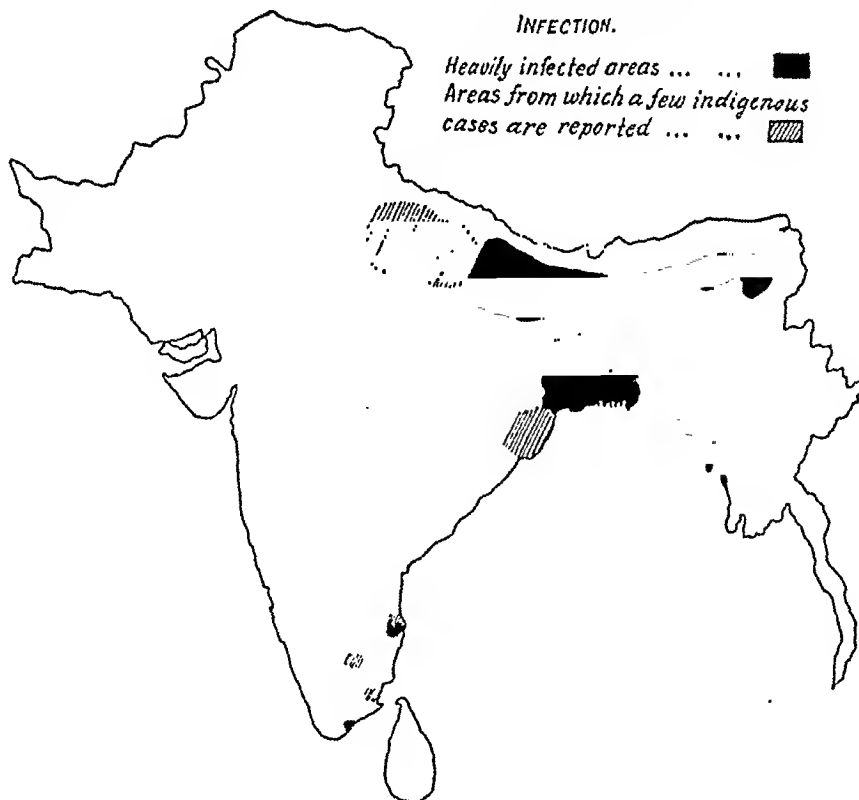

*Sir U. N. Brahmachari Memorial Lecture, Royal Asiatic Society of Bengal.

workers. Some interesting examples of the dangers of partial correlation were displayed when Giles (1892) finding the hookworm ova in the stools of every case affirmed the disease

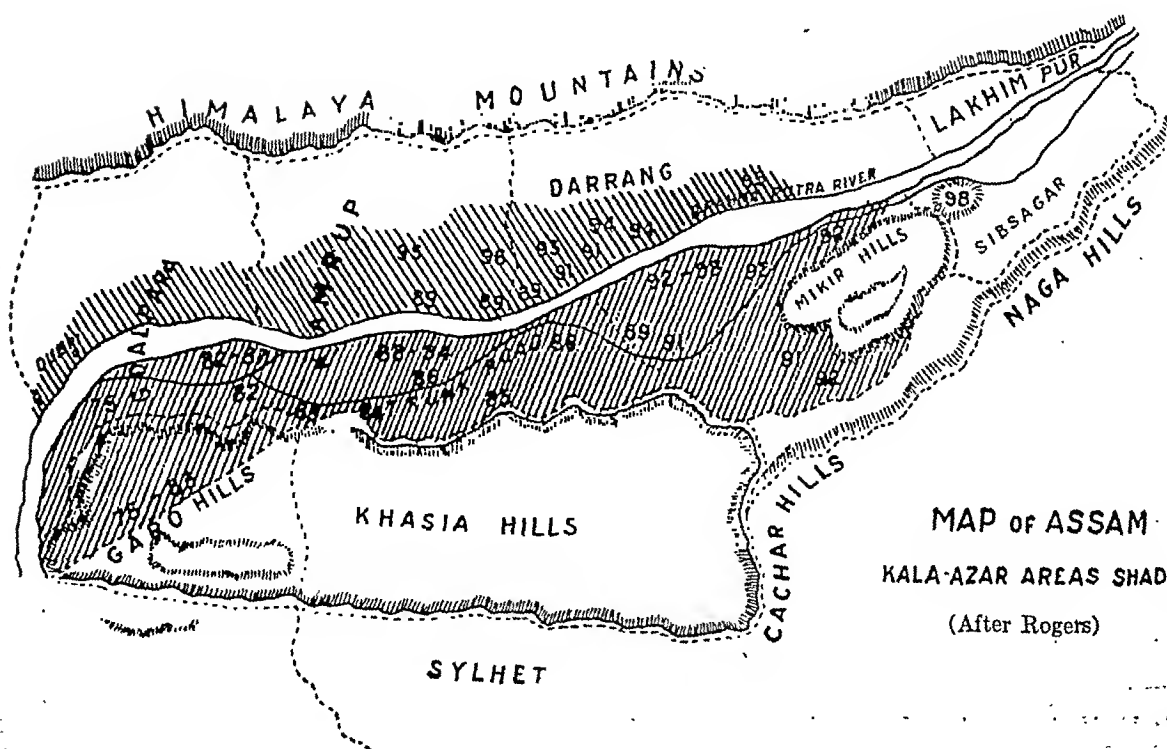

to be ankylostomiasis and later Rogers (1897) and then Ross (1899) concluded that it was a severe form of malaria for a parallel reason. Both these infections will be found in almost 100

Map 1.

MAP OF INDIA SHOWING THE
DISTRIBUTION OF KALA-AZAR
INFECTION.

Map 2.

per cent of the inhabitants of some districts of Assam (Napier, 1943).

Recent history. Researches on kala-azar during the twentieth century.—The discovery of the parasite independently and almost simultaneously by Leishman who found it in the spleen of a British soldier who had contracted kala-azar at Dum Dum near Calcutta and subsequently died in England, and by Donovan in Madras in the biopsy material from the spleen of patients suffering from kala-azar, was followed by great advances in knowledge of the various aspects of kala-azar.

Protozoology.—The parasite, *Leishmania donovani* itself, was studied first; and in 1904 Rogers and later G. C. Chatterjee cultivated the parasite in artificial medium and described the flagellate form that develops on culture of the oval form from the spleen or the peripheral blood. Further studies by various protozoologists in India, viz, Christophers, R. Row, Shortt, Mackie, Knowles, B. M. Das Gupta, J. C. Ray and others, provided comprehensive knowledge on the morphology, cultural characters and other protozoological features of this parasite.

Pathology.—The morbid changes in the body caused in kala-azar were first studied by Christophers in 1904. Of the later studies of the pathology of kala-azar in India, that of M. N. De deserves special mention because of the important contributions made to this subject.

Clinical features.—The clinical picture of the disease was further clarified by the work of Rogers, Muir, U. N. Brahmachari, Napier and others. A peculiar cutaneous sequel to kala-azar was first described by U. N. Brahmachari in 1922. He called this condition 'dermal leishmanoid'. This condition (post-kala-azar dermal leishmaniasis) was further studied by Shortt and Brahmachari, Acton and Napier, Knowles and B. M. Das Gupta, Smith, C. R. Das Gupta and other workers of the Calcutta School of Tropical Medicine.

Epidemiology.—Epidemiological studies of considerable interest on kala-azar in India were also carried out by different workers during the first thirty years of the present century. In the nineteen twenties outstanding contributions were made by the workers at the School of Tropical Medicine, Calcutta, headed by Napier, and by the Kala-azar Commission of India.

Diagnosis.—The first of the diagnostic serum tests, a globulin precipitation test, was described by U. N. Brahmachari in 1917. This test has proved of value in North China but in Bengal where there is so much malaria this test has not proved to be very specific. About 1921 various workers noted that in kala-azar the blood serum when treated with formalin gave a peculiar reaction. This became the basis of Napier's aldehyde test for kala-azar. This test has proved to be of great value in the diagnosis of chronic kala-azar. In 1927 Chopra, J. C. Gupta and David first described the antimony test. Subsequently Napier standardized the technique of this test

too. This test is of value in the diagnosis of cases of kala-azar with small splenic enlargement and of duration of over two months. In 1936 a South American worker first noticed that a positive complement fixation reaction was obtained with the Witebsky, Klingenstein and Kuhn (WKK) antigen in leishmaniasis. This finding was confirmed by Greval, Lowe and their associates (Greval, Lowe and Bose, 1939, Lowe and Greval, 1939) for Indian kala-azar. In 1939 Greval, Sen Gupta and Napier developed a technique of complement fixation test of high degree of 'specificity' and sensitiveness for kala-azar using the WKK antigen. Dharmendra next showed that similar antigen could be prepared from various acid-fast saprophytic bacilli and this gave a positive reaction with kala-azar serum. The test was further worked out by Sen Gupta (1944) and a modified technique was described by him next year (Sen Gupta, 1945). This test has proved to be of great value in the diagnosis of kala-azar and positive indication of kala-azar is usually obtained as early as the third week of illness.

The methods of demonstration of the parasite were developed soon after the discovery of the parasite; and techniques of demonstration of these in the peripheral blood, splenic puncture material, by cultural methods, etc., were described. The important recent advances were Napier's invention of a special spleen puncture syringe and the adoption of the Salah Pattern sternum puncture needle for sternal biopsy in suspected cases of kala-azar. With the former the parasite could be demonstrated in about 95 per cent of cases and with the latter in about 85 to 90 per cent.

Treatment.—Previous to the introduction of the specific treatment for kala-azar, the mortality rate was near about 90 to 95 per cent. It was in 1913, that a South American worker first reported success in the treatment of espundia, a leishmanial disease, with tartar emetic. Di Cristina and Caronia in 1915 first treated kala-azar in Italy with tartar emetic injections and obtained successful results. In the same year Rogers and Muir used this drug in Indian kala-azar.

The treatment of kala-azar with antimonyl tartrates was further developed and standardized by Knowles, Brahmachari, Muir, Napier and other workers in Bengal and Assam. The introduction of the tartrates was a great advance in the treatment of this disease, because about 70 per cent of the cases could be cured with this drug. There were however many disadvantages, viz, too long a course of treatment, frequent occurrence of unpleasant reactions, relapses and resistance to treatment, etc.

The next group of antimony compounds to be introduced were the pentavalent aromatic antimonials. H. Schmidt first introduced *p*-acetyl-aminophenyl-stibinate of sodium in 1915 for the treatment of kala-azar and Caronia first reported success with this compound.

Later work in India showed that this compound was not satisfactory. In 1922 U. N. Brahmachari prepared urea stibamine, a compound of urea and *p*-aminophenyl-stibinic acid. This drug was proved to be of value in the treatment of kala-azar by Brahmachari, then by Shortt and Sen, and later by Napier. It has been found by workers in all kala-azar areas of the world to be a very powerful therapeutic agent and one of the very best pentavalent antimonials. Numerous other antimony compounds, trivalent and pentavalent, were tested in India mainly by Napier. Of these compounds neostibosan, diethylamine-*p*-aminophenyl-stibinate, was found to be very satisfactory by Napier. The cure rate of Indian kala-azar with pentavalent antimonials in general was 95 per cent. Thus a disease of over 90 per cent mortality could be cured in 95 per cent cases. This was a remarkable achievement indeed.

The introduction of the aromatic diamidines in the treatment of kala-azar forms an important landmark in chemotherapy. Stilbamidine, 4:4'-diamidino stilbene, was synthesized by Ewins in 1939. It was used with success in the treatment of a case of Indian kala-azar by Adams and Yorke in Liverpool in the same year. During 1940 to 1941, Napier, Sen Gupta and Sen treated 101 cases of Indian kala-azar with this drug and obtained a cure rate of 98 per cent. The drug was found to be equally successful in the treatment of antimony-resistant cases of kala-azar. A neurological sequel to the administration of diamidino stilbene was first described by Napier and Sen Gupta in 1942. This finding was later confirmed by Kirk from Sudan in 1944.

Several other aromatic diamidines have been tested at the Calcutta School of Tropical Medicine, but none has been found as effective as the first compound stilbamidine.

Other important advances made were in connection with the treatment of seriously complicated cases of kala-azar. Pulmonary tuberculosis complicating kala-azar was regarded by Napier as a fatal combination, on account of the fact that the lung condition was adversely affected by the specific treatment for kala-azar. Sen Gupta (1944) showed that in such cases stilbamidine could be used for the cure of kala-azar without causing any ill effects on the tuberculous disease of the lungs. The treatment of cancrum oris, the classical and most fatal complication of kala-azar, was very unsatisfactory. The use of penicillin (Sen Gupta and Chakravarty, 1945) in the treatment of this condition during the recent years has been found to yield very satisfactory results.

Transmission of kala-azar.—Ever since the discovery of the parasite the problem of transmission of kala-azar has been of interest to all workers on this disease. It was strongly suspected that a biting insect was the transmitting agent. Rogers suspected the bed bug to be the insect vector. Patton showed that the parasite underwent some development in the intestinal

tract of the bed bug, and affirmed his belief that this insect was the transmitter of kala-azar. Later work has, however, completely disproved this hypothesis.

In 1913 Mackie suggested that the sandfly ought to be studied in connection with the transmission of kala-azar. Mackie, however, was able to find only *Phlebotomus minutus* that rarely bites man and hence there was little encouragement to follow his suggestion. Acton (1919) considered that the sandfly was concerned with the transmission of kala-azar; he based his opinion on his observations on oriental sore in Iraq.

With the opening of the Calcutta School of Tropical Medicine, a fresh start of the study of the transmission problem was made by Knowles, Napier and B. M. Das Gupta.

The epidemiological studies of Napier helped to narrow down the investigations to a particular area of the town. Smith was appointed as the medical entomologist to work with this enquiry. It was found that, except the ubiquitous bed bug, of the insects most constantly present in the affected area, the sandfly, *P. argentipes*, was the persistent human blood feeder. These workers of the Calcutta School of Tropical Medicine were impressed by the finding of this sandfly in the kala-azar area of Calcutta and in answer to an enquiry by Knowles on the subject of sandflies in the kala-azar areas, Sinton pointed out that *P. argentipes* appeared to have a distribution in India corresponding to that of kala-azar. At the time, however, this sandfly had not been reported from Assam and Madras. Knowles, Napier and Smith (1924) showed that 40 per cent of the laboratory-bred sandflies fed on cases of kala-azar developed a heavy infection with the flagellates in their midgut. In the same year the Indian Research Fund Association Kala-azar Commission with Christophers, Shortt and Barraud commenced work in Assam. Following up the observations made at the School of Tropical Medicine, they devoted considerable attention to the sandfly, and were able to confirm the Calcutta findings. They also showed that the infection in the sandfly progressed towards the mouth parts, so that if the fly took another blood meal it would in all probability contaminate the wound with flagellates. The progress of the researches was considerably helped at this stage by the discovery by Young, Smyly, and Brown in 1924 that the Chinese hamster was very susceptible to leishmania infection. The work on the transmission of the disease to the hamster by the bite of the infected sandfly was taken up enthusiastically by all the workers interested in the problem. The results of these attempts to transmit the infection by the bite of the sandfly were singularly disappointing. Though Shortt, Smith, Swaminath, and Krishnan (1931) and Napier, Smith and Krishnan (1933) and Smith *et al.* (1936) succeeded in transmitting the infection to a few hamsters out of several hundreds of animals, it

was the many failures that needed explaining, and all attempts to transmit to human volunteers were entirely unsuccessful.

The Kala-azar Commission was disbanded in 1931, and a lull in the research activities on this subject followed. In 1939, Smith was once again appointed by the Indian Research Fund Association and worked in Bihar where there was a recrudescence of the disease at the time. He was able to make a number of very important observations. He showed that survival and the progress of infection depends on whether the sandfly takes a second blood meal or subsists on fruit or plant juices. In the latter case, a large percentage of the infected flies develop a massive infection with leishmania which blocks the pharynx and the buccal cavity; when these blocked flies were fed on a susceptible animal such as the hamster or the white mouse, infection almost invariably followed. The perfection of the technique of keeping the sandflies alive for longer periods, producing 'blocked' sandflies almost at will, and transmission of the disease to a large proportion of the susceptible animals were the outstanding contributions of Smith, Halder and Ahmed (1941). Smith was unfortunately recalled on military duty in 1941, and the final experiments on human volunteers were carried out by Swaminath, Shortt and Anderson (1942) who succeeded in transmitting kala-azar to five out of six human volunteers by the bite of the blocked sandfly.

This final experiment, along with the epidemiological data and the knowledge about the bionomics of the sandfly, led to the conclusion that the usual method of transmission of kala-azar is by the agency of the sandfly *P. argentipes* in India and by other species of the sandfly elsewhere.

The solution of the kala-azar transmission problem is an achievement of medical research in India and is the outcome of years of strenuous work by the research workers of the Calcutta School of Tropical Medicine, the Kala-azar Commission, and other kala-azar research units of the Indian Research Fund Association.

On recapitulating the work done on kala-azar in India it will be noted that on almost all aspects of the disease very important contributions have been made by the different research workers in this country.

The causation of the disease, its clinical features, the morbid changes caused by it, the epidemiological factors responsible for the causation of the disease, the methods of diagnosis, synthesis of drugs that can cure 95 per cent of cases, the method of its transmission, have all been worked out by workers in India. Also the bionomics of the vector, the action of the various insecticides on it have also been worked out.

Present position of kala-azar in India.—From the above account it will be apparent that all probable methods of conquest of kala-azar are known. Also some work has been carried out in

order to establish the hypothesis that the treatment of all cases in an endemic area can lead to the control if not eradication of the disease in the area. The fact that the modern insecticides such as a DDT, pyrethrum, etc., are effective against the sandfly is also known. But little has been done by the State to utilize this knowledge, and the disease is far from under control.

In Bengal, the recorded incidence of kala-azar (which is probably a fraction of the actual incidence of the disease) has been more or less steady for twenty years during 1924 to 1943. Though the disease was showing signs of regression in certain districts in West Bengal, a study of the figures relating to the incidence carried out by Sen Gupta (1944a) showed that the trend of incidence was towards an increase in a number of districts in East Bengal, particularly in Chittagong, Dacca and Faridpur districts. By the end of 1944 and the beginning of 1945, marked increase of incidence was noticed in those districts. From certain data available at present it appears that there has been a widespread increase of incidence in different areas of Bengal. Even in Calcutta where a well-marked focus of infection was discovered about 25 years ago, the disease is not only more prevalent in that area but it has spread to other areas of the town as well.

In Assam there has been outbreaks of kala-azar in epidemic form on several occasions. In Bihar there was an epidemic of kala-azar in 1939 to 1941. The incidence is probably fairly high in certain districts of that province. No epidemics have been reported from South India during recent years.

It may seem strange and depressing that now with all our knowledge of kala-azar, its cause, diagnosis, treatment and prevention, kala-azar should persist in such large amount in many parts of North-East India and that it should actually be increasing at the present time.

It should be remembered that some of this knowledge has only recently become available, and that the application of this knowledge on a wide scale has been handicapped by war and famine conditions which moreover have probably helped to cause the increase in kala-azar.

It is to be hoped that in the near future a better public health and medical relief organization will come into operation and it will be possible to apply the knowledge about the prevention and cure of diseases to the whole country. Then only we may expect to control and even to eradicate the diseases of this country.

Medical News

BRITISH CHEMICALS AND THEIR MANUFACTURERS, 1946

A copy of the above publication has been sent to us by the Association of British Chemical Manufacturers, 166 Piccadilly, London W.1. This Directory, includes up-to-date information regarding the manufacturers of all types of chemicals, e.g. heavy, fine, pure, etc., and supersedes both the old Directories published by the Association. A copy will be sent gratis to any inquirer writing on business paper or giving any other genuine indication of his being likely to put the Directory to good use as a purchaser of chemicals.

The Association has opened a Branch Office for India at Janmabhoomi Chambers, Fort Street, Ballard Estate, Bombay 1. All inquiries should be addressed to the Bombay Office.

JOURNAL OF THE INDIAN ANTHROPOLOGICAL INSTITUTE. VOL. 1 (NEW SERIES), 1945

This issue consists of valuable articles by eminent authors namely Dessication of Asia by Sir Aurel Stein, A Survey of Ancient Gandhara by M. E. and D. H. Gordon, Archaeological Miscellany by D. H. Gordon, Megalithic Monuments of Southern India by A. Aiyappan, and Gond Exogamy by M. P. Buradkar. They comprise highly interesting and extremely useful investigations recorded by actual painstaking field work on a geographical question in the light of history depicting the mutual relationship of the activity of man and nature (how the damage done by man is made good by nature), archaeological contents from sites of antiquity and ancient cultures with outlined sketches of paintings and engravings, exogamy of a primitive type which may have an important bearing genetically as to the advisability or otherwise of the marriage of blood relatives (to avoid incest). The

findings admirably indicate how cultures in early times were already far more differentiated than has hitherto been thought of. The journal is informative and complete with illustrations, map and bibliography. This type of journal is of interest not only to anthropologists, archaeologists and prehistorians but also to the social biologists, psychologists and geneticists. It is hoped that a regular publication of this exceedingly useful journal will stimulate anthropologists, present and future, to explore further for the growth of the national life of India.

USE OF 'HUMAN GUINEA-PIGS' IN PRESSURE CHAMBER TESTS BY NAZIS

(Abstracted from the *Journal of American Medical Association*, 14th September, 1946, p. 84)

ARMY Air Forces Headquarters has disclosed after study of captured enemy medical reports that 'human guinea-pigs' were successfully used in German pressure chamber tests up to 30,400 feet without oxygen. The research was carried out in German laboratories in the Dachau internment camp by Nazi scientists and doctors during April 1942. Tests were made on human subjects at the direction of Heinrich Himmler, Gestapo chief. Records in the Office of the Air Surgeon reveal that tests placed human beings at a higher artificial altitude without oxygen than ever before reached. The U.S. Navy in operation 'Mount Everest' raised volunteer personnel to 29,025 feet.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY, CALCUTTA UNIVERSITY

THE first course of lectures as required for both parts of the Diploma in Ophthalmic Medicine and Surgery Examination of the University of Calcutta started at the Eye Infirmary, Medical College Hospitals, Calcutta, on 5th May, 1947.

The subjects include the following :—

Part I—Anatomy,	Part II—Pathology.
Physiology.	Bacteriology.
Optics.	Ophthalmic Medicine.
	Medical Ophthalmology.
	Ophthalmic Surgery.
	Operative Surgery.

The following are giving the lectures :—

- Capt. E. J. Somerset, M.S. (Lond.), I.M.S., Professor of Ophthalmology, Medical College, Calcutta.
- Dr. S. C. Sinha, F.R.C.S. (Edin.), Professor of Anatomy, Medical College, Calcutta.
- Mr. T. Ahmed, F.R.C.S., D.O.M.S., Hony. Ophthalmic Surgeon, Medical College, Calcutta.
- Capt. K. Sen, F.R.C.S., D.O.M.S., Hony. Ophthalmic Surgeon, Medical College, Calcutta.
- Dr. B. K. Das Gupta, F.R.C.S., D.O.M.S., Hony. Junior Visiting Surgeon, Eye Infirmary, Medical College Hospitals, Calcutta.
- Dr. P. K. Guha, M.R.C.S., L.R.C.P., D.O.M.S., Hony. Junior Visiting Surgeon, Eye Infirmary, Medical College Hospitals, Calcutta.

TRAINING OF PROBATIONER NURSES IN U.K.

THE following ladies have been selected for training as Probationer Nurses in the U.K.

Centre

- Miss Aansuya Subramaniam.
Miss Nasim Farhat Ahmed.
Miss Masuda Bhatti.
Mys. Sarla Anand.
Miss Khurshid Butt.

United Provinces

- Miss Mary Clara Xavier.
Miss Beatrice Doreen Ghose.

Punjab

Miss Munawar Fateh.
Miss Sharanjit Kaur.
Miss Kumari Sanyokta Bhatta.

Central Provinces

Miss Teresa Hackett.
Miss Indumati Deshpande.
Miss D. Lazarus.

Orissa

Miss I. M. Samuel.

Bengal

Miss Lillian Nomita Biswas.

Madras

Miss H. M. Hurtis.

Bombay

Miss Sarala Bakaya.

Arrangements for placing the candidates in suitable institutions in U.K. are being made and the candidates concerned will be informed about the arrangements in due course.

HEALTH DEPARTMENT,
NEW DELHI,
20th June, 1947.

'PALUDRINE'—INDIA, JUNE 1947

Issued by Imperial Chemical Industries (India), Ltd.
Medical Services Department, June 1947]

THE undernoted dosage recommendation made by the Imperial Chemical Industries, Ltd., as a result of the clinical trials which have been carried out in India during last year, 1946-47. These definite recommendations supersede the suggestions made in leaflet reference—TII.—Printed in England—No. 240620-1/25/946'.

Treatment of Malaria with 'Paludrine'

Clinical cures of all types of malaria can be obtained by single doses of 'Paludrine'. It is recommended that a 'single-dose' treatment of 0.3 gm. (three tablets) should be given to achieve clinical cure.

To obtain a radical cure of malignant tertian malaria 0.1 gm. (one tablet) three times a day for ten days should be given. This treatment can be shortened, if so desired, by giving larger doses over a correspondingly shorter period.

The radical cure of benign tertian malaria is still being investigated. Present knowledge indicates, however, that if the co-operation of the patient can be obtained the acute attack should be controlled and then 0.1 gm. (one tablet) should be given twice weekly at spaced intervals for six months.

Protection against Malaria through 'Paludrine'

One tablet (0.1 gm.) twice weekly at spaced intervals (e.g. Wednesdays and Sundays) will give complete causal prophylaxis against malignant tertian malaria. 'Paludrine' is the only drug which will achieve this effect in easily tolerated doses. This treatment also gives effective clinical prophylaxis against benign tertian malaria.

If for any reason twice weekly dosage is not possible, a very good degree of protection can still be expected from one tablet (0.1 gm.) given only once per week. Should, however, hyperendemic malarial conditions prevail, and the once weekly routine is preferred, the dose must be increased to three tablets (0.3 gm.) each week.

Children's Dosage

It is recommended that, both for treatment and protection, children above 10 years should be treated as adults. In the case of children under 10 the dose

should be individualized according to age and size, but no child need be given less than 0.025 gm. ($\frac{1}{4}$ tablet).

FOURTH INTERNATIONAL CANCER RESEARCH CONGRESS, ST. LOUIS, MISSOURI, U.S.A., 2ND TO 7TH SEPTEMBER, 1947. HEADQUARTERS: JEFFERSON HOTEL, 415 NORTH TWELFTH STREET, ST. LOUIS

SPONSORED BY UNION INTERNATIONALE CONTRE LE CANCER AND THE AMERICAN ASSOCIATION FOR CANCER RESEARCH

Programme

DR. SHIELDS WARREN, New England Deaconess Hospital, Boston, Massachusetts, is Chairman of the Programme Committee. Dr. Sidney Farber of Harvard Medical School is Vice-Chairman. Other members of the committee are: Dr. V. R. Khanolkar, Bombay, India; Dr. J. Maisin, Louvain, Belgium; Dr. John J. Bittner, Minneapolis, Minnesota; Dr. Ingacio G. Guzman, Mexico, D.F.; Dr. Walter M. Simpson, Ann Arbor, Michigan; Dr. Alexander Haddow, London, England; Dr. A. Lipschultz, Santiago de Chile, South America; Dr. Arthur W. Ham, Toronto, Canada; Dr. Antoine Lacassagne, Paris, France.

Two types of scientific sessions are planned: (1) Long papers by invitation of the Executive Committee of the Congress on selected topics, and (2) short papers, titles of which should be submitted by those desiring to participate in the Congress.

The general sessions (invitation programme) will include presentations on the following topics:—

- Sept. 3—1. General Aspects of Cancer Research; Cancer Surgery; Radiation Therapy of Cancer.
2. Aetiology of Cancer.
- Sept. 4—3. Aetiology of Cancer (Carcinogens).
4. Chemistry in Relation to Cancer.
- Sept. 5—5. Hormones and Cancer.
6. Biology of Cancer.
- Sept. 6—7. Nuclear Physics in Relation to Cancer.
8. Cancer and the Host.

Persons desiring to present papers should submit titles and abstracts of not more than 250 words to the Chairman of the Programme Committee before 1st July, 1947. Titles and abstracts should be in English. The Programme Committee reserves the right to accept or reject such papers.

Manuscripts of the papers presented should be submitted at the Congress for publication. Manuscripts in English, French, German, Russian or Spanish will be acceptable.

Exhibits

Dr. G. W. Larimore, American Cancer Society, 47 Beaver Street, New York 4, New York, is Chairman of Exhibits Committee. Sub-Committee Chairmen assisting Dr. Larimore are as follows:—

Dr. Bruno Gebhard, Dr. Sherwood Moore, Dr. Roy Hertz, and Dr. Philip S. Owen.

Titles and brief descriptions (not over 250 words) of exhibits should reach the Chairman by 1st July, 1947:—

1. Emphasis should be put on (a) results of laboratory and clinical research on cancer; (b) the materials and equipment used in cancer research; and (c) organizations promoting cancer research.
2. Exhibits should be as dynamic as possible. Attempts will be made to provide apparatus and such facilities as may be required for special display of animals, microscopic preparations, films, etc.
3. Commercial organizations may help in providing equipment for individual exhibits but space will not be available for strictly commercial exhibits.

Attendance and Regulations

All investigators or persons interested in cancer research are welcome. A registration fee of \$10.00 will be charged of all attending the Congress except the official delegates.

Schedule of Events (subject to change)

- Monday, Sept. 1—(Labour Day, An American Holiday). Arrival of delegates.
- Tuesday, Sept. 2—A. Registration.
 B. Visit to the State Cancer Hospital, Columbia, Missouri. (Transportation by motor bus will be arranged by Dr. Arneson for those making reservations not later than 1st September. Leave at 10 a.m., return at 5 p.m. Round trip—250 miles.)
 C. 9-30 a.m.—Meeting of delegates in Room 4, Floor 3, and election of officers, chairman and secretary.
 D. 2-00 p.m.—Business meeting of delegates.
 E. 8-00 p.m.—Reception.
- Wednesday, Sept. 3—A. Scientific sessions and meeting of delegates.
 B. 7-00 p.m.—Dinner. Message from President Truman. Brief welcoming addresses by Governor, Mayor and others.
- Thursday, Sept. 4—A. Scientific sessions, meetings of delegates and visits previously arranged.
 B. 7-00 p.m.—Dinner. Symposium on cancer research.
- Friday, Sept. 5—A. Scientific sessions, meetings of delegates and visits previously arranged.
 B. 7-00 p.m.—Dinner. Discussion on organization and financing of cancer research.
- Saturday, Sept. 6—A. Scientific sessions, meetings of delegates and visits previously arranged.
 B. 7-00 p.m.—Dinner. Reports of delegates.
- Sunday, Sept. 7—A. Concluding meeting of delegates.
 B. Motor trip to the State Cancer Hospital.

Executive Committee

This Committee consists of the President of the Congress, Dr. E. V. Cowdry, Barnard Free Skin and Cancer Hospital, St. Louis 3, Missouri, and the chairmen of the main committees listed above. Dr. J. Godart, President of the Union Internationale Contre le Cancer, and Dr. J. J. Bittner, President of the American Association for Cancer Research, are members *ex-officio*.

The office of the Executive Committee will be in the Art Gallery, Floor 2, of the headquarter's hotel.

FIFTH ALL-INDIA OBSTETRIC AND GYNÆCOLOGICAL CONGRESS

The Fifth All-India Obstetric and Gynæcological Congress will be held at Bombay from the 25th to 28th December, 1947.

The subjects for discussion will be :—

(1) Dystocia, (2) Sterility, and (3) Neonatal deaths; besides other scientific papers, demonstrations and exhibitions.

SIR ALMROTH EDWARD WRIGHT (1861—1947)

By PROFESSOR A. M. LOW

(From Release No. F.710, dated 24th June, 1947, offered by the United Kingdom Publicity Services, New Delhi)

Few people realize that the laboratory in which penicillin, the 'wonder' drug, was first discovered, was also the workshop of another great medical researcher, Almroth Wright, who served on the Indian Plague Committee and did all in his power to alleviate the frightful outbreaks of typhoid raging amongst troops in India towards the end of the last century.

The work of Almroth Wright, who died on 30th April, 1947, in Britain, was begun 50 years ago at the Army Medical School, Netley. He was the originator of the system of anti-typhoid inoculation for bacterial infections, known as vaccinotherapy, which was responsible for saving millions of human lives, both soldiers and civilians.

Throughout his long life Almroth Wright was a hunter and destroyer of those deadly microbes that wage unceasing war on human beings. His success can easily be gauged by comparing the lives lost by typhoid fever before his discovery and methods of immunization were available.

In the Boer War, except where Wright's methods were carried out—in face, be it said, of opposition from those in authority—more men died of fever than were killed in action. In World War I only half as much typhoid was recorded and only one-seventh the number of deaths.

Travelling prize winner.—In the Franco-Prussian War one German soldier in 16, it is stated, caught typhoid fever, against a figure of one in every 900 of the British troops in World War I.

Almroth Edward Wright was the son of a distinguished Irish clergyman and a Swedish mother. Educated on the Continent and then at Trinity College, Dublin, he soon proved his high intellectual ability and won a gold medal in modern literature.

From Dublin, Almroth Wright went to London, where he began to study law, but when later he gained a medical travelling prize at Dublin, he discarded legal training for further studies on the Continent, where he stayed at Leipzig, Strasbourg and Marburg, finally returning to Ireland and taking his M.B., B.Ch., and M.D. degrees at Trinity College, Dublin.

Medicine was his chosen career, and after indulging in original work at the Royal College of Physicians, Wright was offered the post of Demonstrator of Pathology at Cambridge in 1887.

Research on inoculation.—A year later the opportunity arose to visit Australia through his acceptance of the Professorship of Physiology at the University of Sydney. This post he held

until 1892, when he returned to England to work as Professor of Pathology at the Army Medical School, Netley.

Wright's interest had been aroused by certain experiments made on men suffering from cholera by inoculating them with bacteria, and by information published regarding cases of typhoid, also treated by inoculation. He determined to carry out detailed research into the subject of inoculation and into the use of anti-typhoid vaccines.

A few years later, in 1896, Wright published the results of some of his experiments. His theory, on which his work was based, was that healthy blood may not have the germs necessary to fight those attacking the patient, so he introduced vaccine into the healthy blood before inoculating the sick man.

Special department created.—Wright left Netley in 1902 to take up an appointment as Pathologist at St. Mary's Hospital, London. There he created a special department of therapeutic inoculation, later to be re-named the Institute of Pathology and Research. Up to the last year of his life Wright visited St. Mary's to work in this department, and for 40 years, so it is said, drew a small amount of his own blood daily for experimental purposes.

During the First World War he served in France as Consulting Physician to the British forces, and provided during the four years of war enough anti-typhoid vaccine for 4,500,000 persons.

He also worked on treatment of wounds and obtained satisfactory results by using solutions containing no antiseptics, in distinction to the Carrel-Dakin method, which kept the wound continually in an antiseptic bath and drained away the pus.

That great British scientist, Sir Alexander Fleming, discoverer of penicillin, was a pupil of Almroth Wright's, and it was in Wright's laboratory that the discovery of the 'miracle' drug took place.

DR. S. N. CHANDRA

DR. S. N. CHANDRA, M.B., Captain, I.M.S. (late), a retired Senior Gazetted Officer in the Imperial Serologist's Department, died on 5th April, 1947.

He had lost his father in his boyhood and had to struggle much as a youth. He graduated from the Calcutta Medical College in 1916 and worked as a House Surgeon in the Medical College Hospitals, Calcutta. After serving in the 1st World War for about 2 years he joined the Imperial Serologist's Department in 1920. He officiated as the Imperial Serologist and Chemical Examiner to the Government of India, and Professor of Serology and Immunology in the School of Tropical Medicine, Calcutta, on several occasions.

He was a very resourceful laboratory man and rendered much help in starting the Blood Transfusion Service and Blood Bank of Calcutta, the first institutions of their kind in India. His colleagues valued his criticism and enjoyed his subtle humour.

He was one of the ardent supporters of the Dramatic Club of the Calcutta Medical College and had been an actor of a very high order.

He leaves behind him his wife, three sons, three daughters and a large number of friends and colleagues to mourn his loss.

He came of the well-known Chandra family of Calcutta.

Dr. Chandra retired in 1945 intending to do many things in his well-earned leisure, including a prolonged stay at Benares.

DR. AMAR NATH GUPTA

DR. AMAR NATH GUPTA, the Dermatologist, passed away at his residence in Short Street on the 10th March, 1947, at the age of 52.

He passed the M.B. examination of the Calcutta University in 1918 and served in the World War I in the Indian Medical Service. On demobilization in 1922, he proceeded to the United Kingdom for post-graduate studies in Dermatology. He returned home in 1923 and commenced practice as a Dermatologist in Calcutta. He was ambitious and a keen seeker after truth. For some time he worked as Honorary Dermatologist in the Howrah General Hospital. Later, when a Dermatology Department was opened in the Carmichael Medical College Hospital and in the Medical College Hospital he was appointed Honorary Dermatologist in both the hospitals.

Dr. Gupta was the Research Scholar of the Calcutta University for two successive terms, and a member of the Executive Committee of the Calcutta Medical Club for a number of years. He read original papers in the Calcutta Medical Club and wrote articles in the *Calcutta Medical Journal*, *Indian Medical Gazette* and other medical journals, which were highly appreciated by the medical profession.

He was of an amiable nature and sociable disposition for which he was liked by his friends, colleagues and students. During the last 3 or 4 years he lived under the shadow of death but attended to his professional duties in the hospital as well as in the practice until 3 or 4 months ago. He bore the pain with great patience and was always cheerful.

He leaves behind his widow and an only child, a girl of 16 years of age. His loss is keenly felt by his friends and colleagues.

BRITISH MEDICAL JOURNAL

22nd February, 1947

THE following extracts from this two-page number will be of interest:—

'This, the smallest *B.M.J.* since 1840, has been "printed" on hand-operated duplicators in B.M.A. House, by permission of the Ministry of Fuel and Power and the C.O.I. Our "printer" this week is the Secretary of the B.M.A.'

'*Coal and medicine.*—Shivering, we tend to think of coal only as fuel. Coal is medicine as well. Runge discovered in 1834 carbolic acid, a coal-tar product. With carbolic Lister stoked the fires of surgery for posterity. Perkin's discovery of the aniline dye mauve in 1856 was the starting point of modern medicine. Weigert in 1871 stained bacteria with the aniline dyes of coal-tar, and Koch soon followed suit. Ehrlich hit upon the idea that certain cells had chemical affinity for certain dyes. This led to differential staining of tissues and the birth of chemotherapy. The red dye-stuff prontosil, patented in 1932, began a revolution in medical treatment—with the sulpha drugs. The malarial remedies, mepacrine and paludrine, depend for synthesis on coal-tar distillates. From naphthalene comes the synthetic analogue of vitamin K. Phenol is the chemical parent of a common purgative, of aspirin, and of the synthetic oestrogen, stilboestrol. Coal gives doctors their most potent remedies and research workers essential chemical instruments. And if nylon that comes from coal is wanted by colliers' wives for stockings the surgeon also wants it for his sutures.

Points from letters.—C. A. Wells says pentothal-curarc anaesthesia gives agreeable induction, complete relaxation, a quiet field, and rapid recovery; G. S. A. Knowles urges use of prostigmin at end of operation to combat apnoea; J. Montgomerie finds hyoseine HBr. 1/100 gr. (0.65 mg.) prevents excessive salivation on recovery from curare. H. W. Barber surprised that our leader (Jan. 18, p. 96) mentions endocrine receptors as new conception, quotes B. Bloch (*Brit. J. Derm. Syph.*, 1931, **43**, 61). D. A. Long believes stomatitis caused by penicillin plus sucrose base, prefers viscous base pastille. G. Hale suggests serum from parent (must have had measles) when no convalescent serum. D. Blatchley says sore throats after "endotracheal" caused by combination of Hg. binitodide antiseptic and amethocaine lubricant. R. J. Brocklehurst thinks many doctors' children at medical schools are unsuitable for medicine. C. K. Robertson says neurological complications in atypical pneumonia treated with sulphonamide may be due to the drug.

Other items in this number are Diary, News, Obituary, Epidemiology, Any Questions and Advertisement Vacancy.

THE CALCUTTA UNIVERSITY (AMENDMENT) BILL AND THE BENGAL UNIVERSITIES BILL

MR. N. C. SEN, M.A., B.L., has sent the following abstract of the above bills for publication. Paragraphs 2 and 4 are of medical interest.

The Calcutta University (Amendment) Bill seeks to democratize the constitution of the Calcutta University. It seeks to abolish the ten Ex-Officio Fellows, and increase the number of Elected Ordinary Fellows from 20 to 75, and fix the number of Ordinary Fellows at the constant figure of 110, of which 30 to be elected by Registered Graduates, 45 to be elected by Teachers, and 35 to be nominated by the Government. Any person may, immediately after graduating in any Faculty, be enrolled as a Registered Graduate (without waiting for 10 years as now prescribed) on payment of a single fee (instead of recurring annual fees). The Teachers shall not be qualified to be elected from the constituency of Registered Graduates. Elections shall not be subject to the approval of the Chancellor. The Vice-Chancellor is to be elected by the Ordinary Fellows and to hold office for 5 years. Every Ordinary Fellow must belong to one and not more than two Faculties. Each Faculty may co-opt members (graduates in that Faculty or persons having special knowledge in respect of the subjects of study represented by that Faculty) not exceeding the number of Fellows constituting the Faculty. All members of a Faculty shall have equal rights. In the Syndicate, all Faculties will be equally represented. Two useful Faculties, viz, Technology and Economics, will be created.

It is obvious that the Bill offers larger and better representation to the Medical Profession in the University than now. Medical Graduates may immediately after graduation be enrolled as Registered Graduates, and will have a larger scope and voice in election of a larger number of Fellows. The enlargement of the Medical Faculty and the election of the majority of the Fellows will offer scope to a larger number of independent practitioners to be associated with the University.

The other Bill, the Bengal Universities Bill, goes a step further. At the first instance, it seeks to declare the Viswa-Bharati at Bolpur and the National Council of Education, Bengal, at Jadavpur as independent Universities. The jurisdiction of Dacca University is to be extended over Dacca Division. The Government Colleges at Hooghly, Rajshahi and Chittagong are respectively to be constituted into independent Universities for Burdwan, Rajshahi and Chittagong Divisions. All recognized educational institutions within the territorial jurisdiction for the time being of every University will be deemed to be affiliated to it. Further, any institution or group of institutions in any area may be incorporated as a new University. A

Board of Education is to be created with equal representatives of the Provincial Government and the several Universities. The function of the Board shall be to co-ordinate work among the Universities in order to avoid duplication of work and expense and help development of the Universities according to the local needs.

It is possible under the Bengal Universities Bill to raise the Medical Schools to the status of Medical Colleges affiliated to one or another of the Universities. The various State Faculties, such as Medical, Ayurvedic, etc., may be merged into the proposed Board of Education with profit. The Calcutta Medical College and the Carmichael Medical College may also be constituted as one or more independent Universities for medical education only, if thought fit. The big Hospitals and other medical institutions may be converted into institutions for post-graduate studies and research and practical training affiliated to one or another of the Universities.

AGAR AGAR FROM INDIAN GRACILARIA

(Abstracted from the *Science and Culture*, Vol. 12, No. 7, January 1947, p. 333)

Gracilaria confervoides, available in the salt water of Chilka Lakes in the east coast of South India, is considered as a suitable raw material for the production of agar agar (*J. Proc. Inst. Chem.*, India, **17**, 1945).

The process for preparing agar involves first in clearing and washing the weed and then extracting it with four times its weight of boiling water for about six hours. The extract is filtered through cloth, poured into shallow enamelled tray and left in a refrigerator overnight. The frozen material is then thawed at about 10°C. and the water decanted. The solidified agar is cut into strips and dried in the sun. Further purification, if required, may be effected by dissolving the material in hot water, decolorizing with charcoal, and freezing the filtered solution. The agar thus produced is found to be satisfactory for culture media in bacteriological work and for use in the preparation of food products.

THE MORALE OF THE SOLDIER

(Abstracted from the *Journal of American Medical Association*, 30th November, 1946, p. 807)

At the Royal Society of Medicine was witnessed the unusual occurrence of a lecture on a medical subject by Field Marshal Montgomery, who delivered the Lloyd Roberts Lecture, on the morale of the soldier. High morale, he said, was a quality without which no war could be won, and it should interest the medical profession because it was a mental product. As a citizen he would reflect the national character, which was therefore of great importance, and anything that weakened this weakened the army. In war the moral stature of some men would increase. Others, under the stress of battle, surrendered to fear and to fatigue and allowed their characters to disintegrate. Morale was a mental quality which maintains human dignity and develops latent heroism. High morale drew a man forward against his own desires. It is not toughness, though tough men may occasionally perform high acts of bravery. Four basic factors are essential to high morale: leadership, discipline, comradeship and self-respect. Good morale is impossible without good leaders; all men are frightened at some time or other to a greater or less extent, and in fear men band together and look for guidance. At such moments they are not capable of standing alone: they find the burden too great. The leader accepts the burdens of others and earns their gratitude thereby and the right to lead them. The quality men recognize in their leader is decision. Fear makes a man sluggish and indecisive. The leader's power over his men is based

Fig. 1.

on his ability to cut through that fear paralysis and to help others to escape from it. His greatest asset is his ability to act normally in abnormal circumstances and to think rationally when his men have ceased to think.

The object of discipline is the conquest of fear. The basis of fear is the awareness of danger, which comes when a man thinks that he is opposed by something more powerful than himself. Discipline helps him to lose his own identity and create a corporate sense. It also implies a conception of duty; but Montgomery thought that this did not embrace abstractions, such as freedom, democracy, empire. A man's sense of duty extended to the friends around him.

This brought Montgomery to his third factor, comradeship. Morale cannot be good unless men come to have affection for one another. Comradeship is the great antidote to fear. Self-respect, his fourth factor, develops if the other three are present. A powerful contributory factor to morale is success; it is not possible to maintain morale during a long period of defeat.

Finally, the Field Marshal returned to his theme that the soldier is first of all a citizen. Nothing weakened a man more than trouble at home. The soldier had to have good living conditions and always good food, but there is a danger of considering welfare as an end. It will never produce high morale by itself because it is essentially soft. Hardness and privation are the school of a good soldier, idleness and luxury his enemies. It was not for nothing that one of the great rallying calls of the British had been the cry 'Blood, toil, tears and sweat'.

OPIMUM SMOKING PROHIBITED

(Abstracted from the *Indian Information*, Vol. 15, No. 198, 15th December, 1946, p. 455)

IN fulfilment of their international obligations and in their earnest desire to co-operate in weaning mankind from a pernicious habit, the Government of India have, in consultation with the Provincial Governments, now decided to prohibit altogether the smoking of opium in British India, exception being made only in favour of existing addicts so long as they survive and subject to their producing medical certificates in terms to be prescribed.

As regards the Indian States, 75 at least have already prohibited or are now prohibiting absolutely the smoking of opium within their territories, while the rest are making declarations on lines similar to that now made by the Government of India.

FORMATION OF AN INDIAN PSYCHIATRIC SOCIETY

FOLLOWING a meeting of psychiatrists in India held in Delhi on 7th January, 1947, it has been decided to form the Indian Psychiatric Society. The purpose and scope of the proposed society is the promotion of mental health among the people of India, including the prevention and treatment of mental disability.

There being, at present, very few psychiatrists in the country, it was decided that initially the society should consist of a small nucleus of practising and qualified psychiatrists, and that other medical practitioners and workers in related social schemes, such as psychology, education, and anthropology, should be invited to participate as members or associate members.

The tasks of the society were realized to include the setting of standards of education and training in psychiatry of doctors generally, and of psychiatrists and their co-workers particularly, and the urgent necessity of stimulating active interest and understanding of problems of mental health among administrative bodies, and the general public.

The first general meeting will be held on the occasion of the next session of the Indian Science Congress.

It is proposed to begin the publication of an Indian Journal of Psychiatry as soon as possible.

Lieut.-Colonel J. E. Dhunjibhoy, I.M.S., was elected the first President of the Society and Major R. B. Davis, D.S.O., I.M.S., of the European Mental Hospital, Ranchi, was made the Secretary.

FOURTEENTH CLINICAL MEETING OF THE CALCUTTA SCHOOL OF TROPICAL MEDICINE HELD ON 5TH FEBRUARY, 1947

DR. G. PANJA showed a Hindu male patient, aged 35, with a cauliflower-like growth on his glans penis and inner surface of prepuce (see figure 1, plate XII). The growth is soft, painless, non-ulcerated and not bleeding on pressure. The external meatus of the urethra is free for urine to pass, though obscured by the growth. No inguinal glands are palpable. No discharge from the meatus seen. General health of the patient is good.

History of phimosis from boyhood; discharge of purulent fluid from the phimosis and irritation inside. Operated one year ago, prepuce was cut off and sutured. No history of venereal disease or sexual intercourse. Recently married. W.R. is negative. Histological examination of the growth shows proliferation of the prickle cell layer of the epidermis and consequent growth of the interpapillary processes into the dermis. Invasion through the basal cell layer, cell-nests and mitotic figures are absent. Parakeratosis is present in the horny layer. Cellular infiltration and dilatation of blood vessels are seen in the upper part of the dermis. Polymorphonuclear cells and micro-organisms are not seen.

Diagnosis.—Papillated growth very similar to venereal wart or condyloma acuminatum. Differential diagnosis was considered regarding epithelioma and granuloma—either venereum or lupoid or syphilitic. Histological picture negatives such a diagnosis. The condition is not likely to be potentially malignant, as it is rapidly improving under x-ray exposure and application of gentian violet lotion. Excision is out of question on account of involvement of the glans.

Such papillated growths have also been seen in two cases affecting the vulva and anus. Injection of filtrate of the smashed growth along with the local treatment is giving encouraging results. It is probable that the condition is due to some filter-passing virus.

Lieut.-Colonel G. Ahmed demonstrated a case of malignant tumour of testis; the patient, aged 22 years, was admitted to hospital on 8th January, 1947, with history of progressive enlargement of the right testis for 5 months, left breast 4 months and right breast 3 months and absence of erection for 3 months. There was a very hard, heavy mass, vertical diameter 12 inches on the right side of the scrotum, inguinal lymph nodes were not enlarged and no para-aortic mass was felt. Breast enlargements were right 3½ inches and left 2½ inches in diameter, soft and not adherent to pectoral muscles. Lower 2/3rd of right lung was dull on percussion and silent on auscultation. Skiagrams revealed opaque shadow of whole of right chest suggesting metastasis and no enlargement of pituitary fossa or calcified patch in the shadow of right testis. Hæmoglobin 65 per cent; white cells 6,000, cholesterol 120 mg. per 100 c.c. Excised tumour of the testis showed nodules of cartilage scattered in great abundance throughout section and cystic spaces containing blood or yellowish glairy fluid; microscopic examination revealed hyaline cartilage, blood vessels and incomplete tubular spaces lined by columnar epithelium. It was a case of teratoid tumour of testis with metastasis in the right lung, with development of opposite secondary sex characters as an interesting feature.

Dr. L. M. Ghosh showed a case with marked hyperkeratosis (cutaneous horns) on the dorsum of the hand and on the dorsum and sole of the feet together with a certain amount of generalized keratosis, angular cheilitis of the mouth and sore tongue. On the face of it the case seemed to be one of avitaminosis or rather dysvitaminosis. The trend of discussion was for carrying on the investigation for vitamin deficiency.

Major Goodall, I.M.S., showed two hæmatological cases. The first case was one of early sub-acute combined degeneration in a Gurkha female, 38 years of age. She had a history of weakness of the legs, gradually progressing since an attack of fever 10 months previously, until she could no longer walk. No history of syphilis, malaria or other illnesses. W.R. was negative. On examination, the patient was seen to be very ataxic, and showed marked inco-ordination with a positive Romberg sign. Weakness was more evidenced in lower than in upper limbs. Reflexes were exaggerated in the lower limbs but the right abdominal reflex was absent. Investigation showed a normal blood picture with slight megaloblastic reaction in the bone marrow. Cerebro-spinal fluid was normal. Differential diagnosis was made from disseminated sclerosis and transverse myelitis, syphilitic. The second case was one of tabes dorsalis in a man of 40 years. He had a history of severe pains and pricking sensations in the legs with progressive weakness during the past 8 months. He was now unable to walk. There was also weakness of the upper limbs. Previous history of untreated syphilis 20 years ago, and malaria. Examination showed him to be extremely ataxic. Pupils gave a sluggish reaction to light. There was weakness of the lower limbs with marked inco-ordination and Rombergism. Muscles were flaccid and showed wasting. There was some sensory loss. Reflexes were absent. Investigations showed his W.R. to be positive both in blood and cerebro-spinal fluid. Lange-gold curve was tabetic in type. Differential diagnosis was made from peripheral neuritis.

Dr. Habibur Rahman showed a case of pseudo-hypertrophic muscular dystrophy in a Hindu boy, aged 12 years. Weakness in his legs and difficulty in moving about were noticed as early as 8 years back, which have since been increasing, and in the last 3 years there has been increasing difficulty in getting up from bed. The father says that the boy developed the disease after an attack of eczema on the legs. The patient is the last but one child of the parents and has two sisters and five brothers living. The first (sister) and the last (brother) died of fever. There is no such disease in the family, nor in the paternal or maternal side. Clinical picture—marked lordosis and winging of the scapulae, gait waddling. The boy stands on a wide base. There is symmetrical and marked enlargement of the calf, thigh and gluteal muscles; girth at calf 13½ inches, at thigh 15 inches. Infra-spinatii are also enlarged. Pectoralis major wasted on both sides. Face normal. When the patient is asked to get up from recumbent posture, he at first rolls his body on to his face, levers up on the limbs and comes to the erect posture by climbing on his thighs as in a typical case of pseudo-hypertrophic muscular dystrophy. Tendon jerks are lost in the lower extremities and very weak in the upper. Treatment with vitamin E produced no appreciable benefit.

Dr. M. Mukherji discussed a case of Richter's hernia strangulated in the first descent in a congenital right inguinal hernial sac. A Hindu male, aged 25 years, cultivator, was brought to the Campbell Hospital on 23rd January, 1947, with severe (colicky?) pain all over the abdomen. Three days previously the patient went to have a stool at midnight. The stool was a constipated one and was followed in a few minutes by colicky pain around the umbilicus. The pain increased and spread all over the abdomen and a cord-like swelling near the right groin was noticed. There were several vomits a few hours later. Next morning the patient noticed that his scrotum was swollen on the right side. No flatus or faeces was passed since the onset of pain.

Gradually the abdomen got distended and the swelling in the scrotum increased. Patient took fluid feeds throughout. There was no vomit since admission. On examination, patient did not look very toxic or dehydrated, tongue slightly moist, pulse 100, blood pressure 120/90, temperature 98.4°F. Abdomen was moderately distended with prominent coils of intestine showing visible peristalsis. Liver dullness was present. Shifting dullness was not present. Auscultation proved increased peristalsis. In the region of the internal abdominal ring and lateral half of the inguinal canal a slight fullness and a small tense swelling (1 inch by ½ inch) were felt. The spermatic cord below the swelling was felt to be thicker than the left. The right side of the scrotum was distended with opaque fluid under low tension. Testes were normal and not painful though the patient gave history of an old orchitis on this side. An enema was given with no result. Under open ether anaesthesia the right inguinal canal was opened. On opening the sac a small bit of intestine was found slightly congested on the lateral side and blood-stained fluid welled up from the scrotal side. The intestine was relieved from the constricting band just below the neck of the sac. About 3 inches of the loop was pulled out from the proximal portions of the intestine. Obviously the mesentery was short and the portion of the gut that was strangled was found to belong to the lowest part of ileum. About three-fourths of the circumference was incarcerated. The sac on the scrotal side was found to be continuous with the tunica vaginalis which contained about 4 oz. of blood-stained fluid. The intestinal wall regained peristaltic movements after warm applications and was replaced into the abdominal cavity. The upper portion of the sac was excised at the neck and the lower half was everted on the testis as in hydrocele operations. The wall of the inguinal canal was not repaired. The patient made an uneventful recovery.

Dr. Sachchidananda Banerjee discussed a case of glycosuria with low renal threshold for glucose associated with hypovitaminosis C. This type of cases is not very common and an error in diagnosis might expose the patient to unnecessary and even harmful treatments. The patient, a 38-year-old Bengali Mohamadan male, tailor, was admitted into the hospital on 16th January, 1947, with complaints of weakness, frequency of micturition and passage of sugar in urine for two months. He told that his father died of diabetes. Routine tests revealed only presence of sugar in urine and no other abnormality. He was fed on a high protein diet—protein 130 gm., fat 90 gm. and carbohydrate 200 gm. On an average the patient passed 1,700 c.c. of urine daily. On the fourth day he was fed 50 gm. glucose in a 50 per cent solution and the glucose tolerance test was done. The patient excreted no sugar in urine when fed glucose, showed a normal fasting blood sugar value and the glucose tolerance test was normal. Although the blood sugar level did not rise above 167 mg. per 100 c.c. blood, he excreted sugar at the end of the test. This indicated that he had a low renal threshold for glucose. He was then fed a high carbohydrate diet—protein 90 gm., fat 50 gm. and carbohydrate 300 gm.—for ten days. Glucose tolerance test was again normal and the urinary excretion of sugar was never more than 5 gm. daily. The vitamin C nutrition of the patient was then studied by estimating the urinary excretion of the vitamin both before and after feeding the patient with a daily dose of 600 mg. of synthetic ascorbic acid (70 mg. per kilo). Before feeding the patient excreted on the average 5 mg. of vitamin C daily and even 3 days after administration, there was no marked increase in vitamin C excretion. In normal individuals a high rise in the urinary excretion of the vitamin is obtained the next day after administration of the test dose. This indicated that the patient was suffering from hypovitaminosis C but he did not show any sign of bleeding gums, petechia, ecchymosis, anaemia, etc. At the time of discharge his weakness and frequency of micturition had disappeared although he was excreting 5 gm. of glucose daily.

THE USE OF GROUND-NUT CAKE FLOUR FOR HUMAN CONSUMPTION*

By M. B. DAVER, M.B., B.S. (Bom.), F.R.F.P. & S.G.,
D.P.H. (Eng.), etc.

*Nutrition Officer, H.E.H. the Nizam's Dominions,
Hyderabad Deccan*

DURING the last war and even to-day, the question of food supplies and of rice supplies in particular is the major problem for the country to solve. India is short of rice. Curtailment of transport facilities, hoarding and speculation have added to the difficulties. Therefore, it is essential to find out some other stuff which could be made available for human consumption with a view to meeting to some extent the cereal shortage. For this reason, the possibility of using ground-nut oil-cake flour, neat as well as mixed with flours or cereals and millets, was considered.

The use of neat flour was tried but had to be given up. The greatest obstacle was 'prejudices' against consuming the so-called 'food for animals' and the belief that it causes diarrhoea, though Dr. Simeons, Director of Public Health, Kolhapur, and Mr. Kincaid of American Presbyterian Mission, Kadoli, used the 'neat flour' in the market for sale; and their report was 'the response from the public was encouraging and they purchased it without any prejudice'.

Then we examined the possibility of using the flour in mixture with maize flour, because both these are articles not rationed and available in good amounts. We tried the mixture in proportion of 60 parts of maize flour and 40 parts of ground-nut cake flour for making various culinary preparations. Out of the flour, biscuits, halva, bhajiyas, ladoos, pakodas and chapatis and even loaves were prepared. These preparations were sold to the public during various exhibitions. The response from the public was excellent, there were no complaints. The public did not suspect that these articles contained ground-nut oil-cake flour.

Later on we made use of the flour in various institutions and boarding houses. The reports said 'there were no complaints on the grounds of taste or indigestion' and the preparations made out of the flour were liked by the inmates.

The flour was used even in most fastidious families for making chapatis and other preparations. They found that the preparations were as good as those made out of wheat or any

other cereal. The only difference was that they were sweetish in taste and therefore required addition of little more table salt.

Later on instead of maize flour we tried flours of cereals, millets or pulses according to their availability or taste. An advantage is that it can be used even in equal proportion; but we found that best proportion was 25 to 30 parts per 100 parts of mixture. In making loaves, it can be used only in 15 parts, if used in higher proportion, it becomes rancid.

From the analysis it is seen that ground-nut cake flour compares very favourably with wheat in its chemical constituents and is superior in vitamin contents, thiamine (B_1) being $12.5 \mu/g.$ and nicotinic acid $27.1 \mu/g.$

Its protein is of high biological value, almost similar to that of meat, besides it is rich in minerals. Thus, it would be an ideal addition to the Indian diets, as most of them are poor in proteins, mineral salts and vitamins, particularly B-complex. Its use can supplement to a great extent those constituents which are deficient in diets of those who do not take meat or egg.

Apart from general reluctance of the people to change their dietary habits, there are three main reasons why ground-nut cake has not hitherto been used for human consumption. First is its smell and second the belief that it causes diarrhoea, and thirdly the fact that they use it as food for animals and not for human consumption.

Its repulsive smell could be removed if only good, graded, selected and handpicked seeds are used. If the skin from the nuts is removed before putting them in the expeller, the cake is whiter in colour and has no smell.

In order to overcome the second difficulty, namely diarrhoea, the press should be used exclusively for ground-nut; it should not be used for pressing castor-oil seeds also.

To get rid of prejudices against its use—as in all other matters—propaganda and a little knowledge in nutrition will be enough. In spite of the additional expenses of picking, removing skin, etc., the flour could be obtained at four seers for a rupee.

This flour should be made popular and put on the market. If public takes to it, there will be proportionate savings in other rationed grains. It will serve three great purposes. Firstly, at cheaper rate the public will have the flour which is as nutritious as any other flour. Secondly, by its use there will be savings in rationed grains. Thirdly, our greatest object of turning the people to consume new food grains will be served.

* Read before the 34th Indian Science Congress held at New Delhi in January 1947.

The Indian Medical Gazette Fifty Years Ago

(From the *Indian Medical Gazette*, Vol. 32,
May 1897, p. 181)

MEDICAL REGISTRATION

AFTER a patient silence of years we return to the important question of the necessity for a *Registration Act* for India, an Act which might be and ought to be introduced without delay into all large towns, and which, after a fair trial, could be extended to provincial areas. We do not ask for any hasty or ill-considered laws, for the matter has already received grave, and in our opinion satisfactory, attention at the hands of the medical profession. If, however, the Government is not satisfied with the evidence before it, surely it would be possible to appoint an intelligent committee to sift the evidence already collected, to examine witnesses and to frame draft rules which could be subsequently shaped into an Act. The importance of this subject was recognized years ago, and in 1881, the medical profession in Bombay drew attention to their desire to have a *Medical Registration Act* for the town and island of Bombay. Their wishes were, in our opinion, on fallacious grounds entirely disregarded, but the Grant College Medical Society attacked the question again in 1887. The Calcutta Medical Society stimulated by the activity of the sister Society discussed the question at a meeting held on 13th July, 1887, and continued the discussion at subsequent meetings. A paper was read by Dr. Birch which gave a most exhaustive review of the situation and left no doubt in the minds of the majority that a very serious evil existed which could only be dealt with by legislation. It was pointed out that nothing existed to prevent the formation of so-called medical schools which pretend to teach medicine 'without dissecting room, library, museum, hospital, diagrams or appliances'. This statement, now ten years old, is true to-day, and is confirmed by the existence of such extraordinary institutions with high-sounding titles making a profit out of what can only be termed 'bogus' diplomas. There can be no doubt whatever that the medical profession, and we speak of both European and native medical men, has a right to demand some protection against unqualified and ignorant men who bring disgrace upon the science and art of medicine and surgery. In dealing with this question some consideration would have to be shown to the large number of unqualified practitioners, kobirajes, baidas and hakims at present plying their trade. They should, however, all be registered, and, after the passing of the *Medical Act*, new additions to their ranks would not be permitted. We need not stop to discuss whether there is any need for the existence of such persons. There is certainly no need for them in

the large towns to which this Act would first apply. Medical aid of a respectable and fairly reliable kind is now available in all large towns throughout India, and for the very poor there is always a hospital at which free medical attendance can be obtained. Surgeon-Colonel Ross in his *Triennial Report on Charitable Dispensaries* has called attention to the fact that 'anyone with a smattering of medical knowledge and even without it can and does set up as a private practitioner' in Bengal; and further that 'there is actually a so-called medical school in Calcutta which grants medical diplomas although it has no charter and is not even affiliated to the University or to any recognized medical institution'.

There are two interests at stake, both worthy of careful consideration. The interests of properly qualified medical men cannot be lightly passed over. When aspirants for medical qualifications learn that, after all their expenditure of time and money, they are on the same footing as the merest quack, their reflections are not likely to encourage others to follow in their footsteps. It is notorious that, so far as Government medical institutions are concerned, the supply of really good men is never equal to the demand. In the interests of the general welfare of the public the Government has a duty to perform and that duty is to give every one who is anxious and willing the means not only of obtaining a proper medical education, but also the means of earning an honest living, by protection against competition with ignorant and dangerous unqualified practitioners. The question affects not only natives and Europeans who have studied in India but also all European medical men who have come out from England and set up in practice in our large towns, and to a less degree all military medical officers whose appointments permit them to engage in private practice. It has been objected that the passing of a *Medical Registration Act* will not put a stop to 'quackery', nor will it prevent a certain minority of qualified men from engaging in disgraceful forms of practice. It would be futile to argue that any such perfect results would ensue. Punishment of offenders would however become easier and more certain. That these results follow the passing of such an Act may be gathered by anyone who will take the trouble to read the proceedings of the Medical Council in England, which are regularly published in the English medical journals. The question next requires consideration from the point of view of the general public. We think that no one will deny that the general public should be protected, as far as possible, from the dangers which accompany the existence of ignorant practitioners of medicine, and the only way to do this is to set forth clearly the diplomas and degrees which carry with them some guarantee that the possessor has been educated in a reliable school of medicine or university.

We have not space to recapitulate the details of the various discussions held upon the question of Medical Registration, but interested readers will find full information in the volumes of the *Indian Medical Gazette*, especially in the Medical Societies in the large cities of India and volume for 1887. We would suggest to the Indian branches of the British Medical Association the desirability of again raising this question with the view of obtaining a Commission of Inquiry, by whose opinion the Government might be guided as to the necessity for action, and the course to be adopted.

LONDON LETTER

THE subject of the excessive prevalence of venereal disease, especially of syphilis, in the European Army in India, continues to engage public and professional attention. A Departmental Committee was appointed in November last, by the Secretary of State for India, under Lord Onslow to report on the case. The facts set forth by this Committee have brought into view the magnitude and seriousness of the matter. 'Venereal disease', the report states, 'directly caused more than one-third of the total amount of sickness in 1895, 15 deaths and 348 invalidings, resulting in 130 cases in final discharge from the service; the constant and total disablement of 3,200 men out of a force of 71,000 men, and a vast amount of partial disablement and unfitness for any but routine duties. Indirectly, it increased the amount of sickness and invaliding under the head of many other complaints. The military efficiency of the army was most seriously impaired, and the increasing prevalence and intensity of contagious and inheritable disease among a body of 71,000 men, of whom many thousands are annually coming home to mingle with the civil population, was a growing danger to the health of the community. The Committee paid a visit to Netley Hospital, and found there a number of young men, disfigured, mutilated and incapacitated for life, whose terrible condition they describe in vivid terms. The Army Sanitary Commission has hitherto declared that the regulations issued and measures adopted under the Contagious Diseases Act in India exercised no repressive effect on the prevalence of venereal diseases in the European Army in India. The rapid and great increase of these maladies—especially of syphilis—since the discontinuance of these measures has convinced the Commission that they did cause a restraining influence, the increase arising during their continuance being due to other circumstances, such as the greater youth of the soldiers and the lower proportion of married men. The Commission has, therefore, strongly recommended resort to preventive arrangements. The Colleges of Physicians and Surgeons and the medical press, together with the more influential organs of the lay press have, with strong and open voice, spoken to the same purpose, and

numerous organizations are being formed to promote these movements; opposition is not wanting nor latent. Various individuals and associations are up in arms, and loudly remonstrate against the adoption of measures of any sort to repress these diseases as being wrong in principle and, as experience has shown, inutile in action. These views, which are not altogether the ravings of hysterical faddists, but also the convictions of earnest good men and women, are entitled to every respect; but a comparison with the case of our own army and that of continental armies demonstrates beyond doubt that repressive measures are efficient, and that the liberty to spread loathsome and dangerous disease, can be, as it undoubtedly ought to be, restrained. The opponents of repression rely too much upon figures which, as is well known, can be variously interpreted and used with plausibility to support opposite positions. The interpretation of these figures constitutes the foundation of much of the controversial writing which appears in the press; but, except as a measure and index of the large amount of disabling disease due to sexual vice, they are of not much administrative value. These totals are made up of a great number of sub-totals representing the state of particular places and bodies of men, and these sub-totals vary much in any one year or series of years, and also from year to year. It requires a special investigation and study of these variations and their causes to understand the case properly. This special inquiry has never been properly made, and it is not clearly known what degree of protection was really conferred by the preventive measures formerly in use according as they were carried out under favourable circumstances and efficiently or otherwise. At the first outcome of all this agitation the Secretary of State for India has sent to the Indian Government an important despatch in which the facts as regards the evils caused by venereal diseases in the army are forcibly stated, and instructions are conveyed that these maladies are to be treated as contagious diseases, the subjects of which, whether men or women, are to be subjected for purposes of segregation and treatment until they cease to be dangerous. The matter is to be worked on the principle of notification of infectious disease, and the manner in which this principle is to be reduced to practise which must depend on the conditions of the country and place, is left largely to military and civil authorities in India, acting under the guidance of the general indications laid down by the Secretary of State. I gather from a telegram published in this morning's *Times* that there is a feeling in India that the action taken by the Secretary of State is timid and inadequate. It may fall short of the requirements of the case looked at from a strictly hygienic point of view, but there are other considerations which a statesman has to take into account, and I am inclined to think that it was wise to proceed cautiously and

tentatively in the matter, and that in so delicate a subject as this is, precipitate and extreme proceedings would probably defeat their own object. Let us hope that the Government of India will be enabled by the present sanction to enact laws and rules which will materially reduce the suffering and disablement caused by these affections.

The Indian Medical Service is to hold its first dinner in London on the 20th of May. The movement has long been mooted; but until this year no opportunity has been offered to members of the service retired and on leave of meeting together socially and spending a pleasant evening in each other's company.

Other services and interests assemble annually in this matter, and the wonder is that the Indian Medical Service has not long ere now instituted a function so popular and useful in this country. A great many men have already signified their intention of joining in the excellent project, and the Indian Medical Service Dinner of 1897

promises to be an unqualified success; and will, I hope, be the commencement of one unbroken series. Sir Joseph Fayrer, Bart., is to preside.

The second volume of Dr. Clifford Allbutt's System of Medicine has just made its appearance. It contains abundant material which ought to be of interest and use to Indian medical practitioners. The articles appear to me to be well written and quite up to date. I am surprised that the *Indian Medical Gazette* has not presented its readers with a review of the first volume which appeared some time ago. The work will take its place as a worthy successor to the late Sir Russell Reynolds' system which in its day had a great reputation and sale. Medical science advances rapidly in these days, and it has been found necessary to append to the present volume important information regarding typhoid fever, plague and yellow fever, which has accrued since the publication of the first volume.

Current Topics, Etc.

Progeria with Nanism and Congenital Cataracts in a Five-Year-Old Child

By R. C. MOEHLIG

(Abstracted from the *Journal of the American Medical Association*, Vol. 132, 16th November, 1946, p. 640)

A CASE of progeria with nanism and congenital cataracts was observed in a five-year-old boy. Progeria with nanism and cataract is not unusual in Werner's syndrome of the adult, but the association of cataracts is a rare condition as a congenital defect. The child was born prematurely and at birth weighed 1,366 gm. His growth was retarded. The cataract of the left eye disappeared spontaneously when he reached the age of 3 years. He was mentally retarded but even at the age of 3 had an unusual talent for music. Methyl testosterone 10 mg. was given in daily doses which resulted in an increase of 17.8 cm. in height and 5 kg. in weight within a period of eight months.

Disseminated Pulmonary Calcification

By ROBERT H. HIGH

HENRY B. SWERLING

and

MICHAEL L. FURCOLOW

(Abstracted from *Public Health Reports*, Vol. 62, No. 1, 3rd January, 1947, p. 20)

DURING the roentgenological survey of various population groups, scattered calcifications in the pulmonary parenchyma have been detected. Some of the army recruits in U.S.A. have been rejected on this score. Hitherto such areas of calcification were considered to be due to healed hematogenous foci of tuberculosis. X-ray studies of groups in the general population have shown distinct geographical differences in the distribution of pulmonary calcification. Further pulmonary calcification has been found frequently in tuberculin negative individuals. But during the last two years a number of papers has appeared in the U.S.A. (*U.S. Public Health Reports*, volumes 60-62) which suggest a mycotic etiology for a large proportion of these cases.

Immunological reactions have been tried with histoplasmin, blastomycin, coccidioidin and haplosporangin. A dependable technique has been evolved by Emmons, *et al.* of the National Institute of Health for the preparation of histoplasmin, whereby non-specific reactions have been largely avoided. Histoplasmin is a sterile broth filtrate of a 5-7 months' culture of *H. capsulatum*. 0.1 c.c. of a 1/1,000 dilution of the filtrate is given intradermally and the result read after 48 hours, indurations of a diameter of 5 mm. and above being considered as positive.

Histoplasmin and tuberculin tests, in addition to chest skiagraphy, have been carried out on different population groups in different parts of the United States. For the benefit of our readers we shall try to give a summary of some of the findings.

These calcifications are more commonly found in the central eastern region, particularly in and near Kansas city. The histoplasmin rate was found to be much higher than tuberculin rates, the whites showing a higher rate than Negroes. In a group of Kansas school children, 12.7 per cent showed definite or probable pulmonary calcification. Among those positive to both histoplasmin and tuberculin, 23.8 per cent showed calcification. Among those positive to histoplasmin but negative to tuberculin, 26.4 per cent; and among those negative to histoplasmin but positive to tuberculin, 11.4 per cent. In the group who were negative to both histoplasmin and tuberculin only 2.6 per cent had calcification. The rate of calcification rises from 4 per cent in the age group 4-6 years to 18 per cent in the age group 16-18 years. In another series studied by High *et al.* (*U.S. Public Health Reports*, volume 62, 3rd January, 1947) noted two types among 113 cases of disseminated pulmonary calcification, *viz.*, a milinary type and a multiple asymmetrical bilateral type. These workers observed that (1) the frequency of calcification rose among the whites from none in the age group under 4 years to 10 per cent in the age group 16-18 years, (2) Negroes showed less calcification than whites, (3) a definite familial relationship was noted, (4) in no instance was such calcification noted among those who reacted only to tuberculin; but in 93.5 per cent of the group, disseminated calcification was noted among reactors to histoplasmin alone.

A. C. U.

THE USES OF VITAMIN E

While the main use of vitamin E up to the present has been the treatment of cases of habitual abortion and sterility of dietary origin (with success in about 70% of cases when whole oil—as in Fertiol—was given) wheat germ oil is being increasingly used for cases of primary muscular dystrophy, amyotrophic lateral sclerosis, anterior poliomyelitis and in rarer cases such as amyotonia congenita.

There are some indications that other factors in Bemax, probably part of the B complex, render the action of vitamin E more effective and it may, therefore, be desirable to reinforce the action of Fertiol in this way.

FERTIOL

Wheat Germ Oil Capsules

A highly active natural and stable source of vitamin E. Each 5 minim capsule is standardized to contain 3 mg. α -tocopherol.

Further particulars concerning Fertiol and Complevite from Martin & Harris Ltd., Mercantile Building, Lall Bazar, Calcutta. Products of Vitamins Limited, London, England.

Complevite

COMPLETE

in the most important vitamins and minerals

BALANCED

to meet known deficiencies in the average diet

CONVENIENT

dosage, in tablet form

ECONOMICAL

— a single supplement for manifold deficiencies

The graph below shows the multiple nature of Complevite tablets and also demonstrates the extent to which Complevite ensures optimal nutrition.

*The iron in Complevite exceeds the calculated deficiency expressly to combat the nutritional anaemia so common in children and in women of child-bearing age.

SEVERE BURN

(Area 162 sq. inches)

A treatment using tulle gras, pressure dressings and plaster fixation

Fig. 1

Fig. 2

CASE HISTORY—The patient, a young man, was admitted to hospital, having been burnt by an electric blanket. The raw area measured 162 square inches. Excision of the burnt area was performed on the same day. Tulle gras (Jelonet) was applied. Fixation by Gypsona plaster of paris bandages applied over the whole area, abdomen and thigh. The patient was given a blood transfusion. Seven days later, the affected part was covered with thin razor grafts from both thighs and a pressure dressing of Elastocrepe applied. Fixation was again secured with Gypsona plaster of paris. The patient was discharged to duty 7 weeks later.

The details and illustrations above are of an actual case. T. J. Smith and Nephew Ltd., Hull, England, manufacturers of Elastoplast, Elastocrepe and Jelonet, are privileged to publish this typical instance of the use of their products with success in the belief that such records will be of interest.

Agent: **RALPH PAXTON, 10, Lall Bazar, CALCUTTA**

TRANQUILLITY

A calm outlook and freedom from worry and nervous tension are rare in these days. The intense application to war work and consequent mental and physical strain are revealed in widespread headaches and insomnia.

Veganin may well be used to soothe the overwrought nerves, relieve pain and induce sleep. It is a synergistic combination of acetylsalicylic acid, phenacetin and codeine, and is widely known as a dependable and highly effective analgesic, sedative and antipyretic. Veganin is neither toxic nor habit forming.

Recent Advances in the Treatment of Epilepsy

By H. HOUSTON MERRITT, M.D.

(Abstracted from the *New York State Journal of Medicine*, 1st December, 1946, p. 2633)

GREAT advances in the treatment of patients with epilepsy have been made in the last decade. The introduction of a new drug, phenytoin sodium, for the control of grand mal seizures has restored many epileptics to their normal place in life and the use of tridione has appreciably decreased the frequency of petit mal attacks in children. A new interest in the treatment of epilepsy has been awakened and it is very probable that more efficient anticonvulsant drugs will be discovered in the near future.

Recent Advances in Rh Testing

By SOL HABERMAN

and

JOSEPH M. HILL

(Abstracted from the *International Medical Digest*, Vol. 49, No. 5, November 1946, p. 260)

IF a potent antiserum of the proper specificity is available the detection of the Rh antigen is a relatively simple procedure. In a series of 1,000 comparative tests between the test tube method and the capillary method of typing, the Chown capillary test showed the same specificity and a greater sensitivity than the tube method.

The anti-human globulin serum is an important serological adjunct to the investigation of iso-immunization whether by pregnancy or transfusion. When the incomplete or blocking antibody is adsorbed on Rh positive erythrocytes, no observable agglutination occurs but the cells are coated with the anti-Rh globulin. The action of this serum is to develop an observable agglutination where the specifically adsorbed antibodies fail to do so. Because of the analogy to the photographic development of a visible image, the writers have suggested that the term 'developing serum' be applied to the anti-human globulin serum.

The following methods for Rh testing are described :
Test for agglutinins.—A 2 per cent suspension of a suitable O Rh positive cell is prepared. One drop of these erythrocytes is mixed with 1 drop of patient's serum in a tube. The tube is placed in a 37°C. water bath for 1 hour. After incubation, the tube is then centrifuged lightly for 1 minute. The tube is lightly agitated and observed under the lower power of the microscope. If clumping occurs, agglutinins are present.

Blocking test for agglutinins.—If the above test shows no clumping, 1 drop of anti-Rh typing serum of known potency is added to the erythrocyte suspension. The tube is again incubated at 37°C. for 1 hour. At the end of the second incubation the cells are observed for agglutination. If clumping occurs, the serum of the patient possessed no blocking antibodies. If no clumping occurs, the patient's serum contained blocking antibodies.

Developing test on patient's serum.—One drop of the serum to be tested is mixed with 1 drop of a 2 per cent suspension of type O Rh positive erythrocytes in a Kahn type tube. This is incubated as before. If no clumping is observed the cells are washed three times. One drop of developing serum is added to the sedimented cells after the saline has been removed. The cells are suspended and incubated for 1 hour at 37°C. The tube is then centrifuged and observed for clumping. Agglutination indicates the presence of adsorbed immune globulin.

Developing test on erythrocytes.—The erythrocytes of cord blood are suspended in saline solution and washed three times and made up as a 2 per cent suspension. One drop of the suspension is added to

1 drop of developing serum in a tube and incubated at 37°C. for 1 hour, centrifuged and observed for agglutination. Clumping of the erythrocytes indicates that antibodies had been adsorbed *in vivo*.

Studies were made on the serum of 5 mothers who had given birth to children having erythroblastosis. In case 1 the agglutinating titre of the maternal serum was very weak and no blocking antibody was demonstrated. However, the developing test showed a titre of 1:64. The cord cells showed a 4+ reaction. In case 2 no agglutinins were found but a blocking titre of 1:2 was present. The developing titre was 1:16. The cord cells were not available because the case was referred from another hospital. In case 3 the mother of a hydrops foetalis showed only 1:2 agglutinating and 1:32 blocking titre in the serum. When the developing test was used her serum showed a titre of 1:2,048. In case 4 the agglutinating and developing titres were equal (1:128) but no blocking antibody was observed. The cord cells showed a 4+ reaction. In case 5 a very weak agglutinin in the undiluted maternal serum was found, but no blocking was observed. The developing titre was 1:64. In this case the cord cells gave a 3+ reaction. In all the cases presented the developing titre equalled or exceeded the agglutinating or blocking titres.

The developing test was applied routinely on all deliveries, and in a period of 62 consecutive days, 424 cord bloods were studied. There were four cases of erythroblastosis, 15 still births, and 1 case of atelectasis. The case of atelectasis is of interest in that the child's blood showed 50 erythroblasts and 20 normoblasts per 100 white blood cells, thus showing one of the laboratory findings associated with erythroblastosis foetalis but due to another cause, e.g. oxygen want. The developing test on cord red blood cells was positive in all the cases with erythroblastosis and negative in the remaining cases of the series.

Penicillin Treatment of Trachoma A Preliminary Report

By D. J. DARIUS

(Abstracted from *Tropical Diseases Bulletin*, Vol. 43, No. 12, December 1946, p. 1182)

DARIUS reported 12 cases of trachoma ranging from type I to the chronic type III treated at the United States Indian Service Hospitals with drops of sodium salt of penicillin in a solution of 500 units to each cubic centimetre of water every $\frac{1}{2}$ hour and 3 hours. Improvement was observed under the three-hour schedule but more rapid results were obtained under a half-hour schedule. Loss of photophobia and lacrimation was noticed in twenty-four to forty-eight hours. Improvement in vision was usually evident on the third day. Beginning shrinking and retraction of vessels of the pannus was definite on the fifth to the seventh day, with accompanying slower clearing of the grey corneal pannus infiltrate. Rapid healing of complicating corneal erosions and ulcers was the most spectacular improvement. The effect is not superior or more rapid than that obtained with sulfanilamide therapy, but penicillin may offer a solution in the treatment of sulfanilamide resistant or sensitive cases.

Siderocytes in Mammalian Blood

Proc. Roy. Soc., Ser. B. 1946, 7th August, y. 133, No. 872, 235-48, 7 figs. (21 refs.)

(Abstracted from *Tropical Diseases Bulletin*, Vol. 43, No. 12, December 1946, p. 1164)

'1. THE siderocyte appeared in large numbers in stored blood and in blood that has been treated with certain chemical agents, e.g. phenylhydrazine.

2. Apparently all erythrocytes went through a stage as a siderocyte, but the granules were extruded, leaving

a cell which was morphologically indistinguishable from a pre-siderocyte erythrocyte.

3. As siderocytes have now been demonstrated in mouse, rat and man (Gruneberg, 1941a, b); in guinea-pig, horse and rabbit (Granick, 1943) and in cat and dog (Case, 1943), the cell is probably to be found in all mammals.

4. After an erythrocyte had become a siderocyte it became susceptible of phagocytosis, and was removed from the circulation in the intact animal.

5. The stainable non-haematin iron was derived from a special fraction of the haemoglobin. Therefore, the iron should be regarded as catabolic, and closely associated with, if not identical with, the E.S.I. described by other workers.

6. The siderocyte is probably the source of the urinary siderotic granules described by Rous (1918).

7. The siderocyte probably has importance in clinical medicine.

Bovine Plasma for Transfusion

(Abstracted from a letter written by J. H. Massons, published in the *Lancet*, 15th February, 1947, p. 272)

THE writer (J. H. Massons) replied to the annotation by Editor, the *Lancet*, on bovine plasma and the letters of Mr. Edwards and Mr. Hughes.

Colloid osmotic pressure.—The annotation suggested that the osmotic pressure of prepared calf plasma (P.C.P.) is less than that of human plasma. With this Mr. Edwards agreed, while Mr. Hughes thought that heating will increase the osmotic pressure. Through lack of suitable apparatus the writer had been unable to follow the changes in osmotic pressure during the preparation of P.C.P.: clinically P.C.P. seemed to exert sufficient osmotic pressure to remain within the vessels, and its administration in hypoproteinaemic oedema is followed by diuresis. Without doubting Mr. Edwards' statement that plasma treated by his method and heated to 100°C. loses its osmotic pressure, the writer suggested that his method differed from Mr. Edwards in the amounts of formal and ammonia added, and it would be interesting if Mr. Edwards' experiments were repeated using the writer's method of preparation.

Antigenic properties.—From Mr. Edwards' letter and paper, heating to 100°C. appeared unnecessary, since agglutinins and haemolysins were inactivated at 72°C. Some antigenic properties were retained after heating at this temperature. With formalized calf serum heated only at 72°C. it was possible to induce fatal anaphylactic shock in guinea-pigs, and to bring about anaphylactic reactions in man. Mr. Edwards did not report any anaphylactic accidents probably due to the fact that few of his patients received more than one transfusion of his bovine serum. Had he been treating patients requiring repeated transfusions at intervals of 5 to 7 days, he might have observed typical anaphylactic crises, and obtained positive Prausnitz-Kustner tests.

The writer was certain that, while hypersensitiveness to repeated injections of bovine plasma heated only to 72°C. is frequent, more than 1,000 ampoules of P.C.P., many of them given at intervals to the same patients, had never produced a reaction of an undoubtedly anaphylactic nature: one reaction encountered was due to sensitiveness to formal. He thus feels justified in stating that P.C.P. is not antigenic.

Fate of P.C.P.—The fate of P.C.P. in the body is not known. Occasionally slight albuminuria (sulphosalicylic acid test), lasting a few days, had been seen after its administration. It is considered probable that most of it was metabolized in the body.

Toxicity.—Mr. Hughes added to the criterion 'non-toxic' a further criterion, the absence of the syndrome attributed to macromolecular substances, such as gum acacia. The point was not investigated but children, who had received multiple transfusions of

P.C.P., recovered uneventfully, and rabbits given repeated injections of P.C.P. (10 c.c.m./kg.) over many months at intervals of 5 to 7 days, remained in normal health. The production, in these rabbits, moreover, of antibodies to injected red cells from *Macacus rhesus* was unimpaired.

Animal plasma as a substitute for human plasma.—It is too ambitious to suggest as in the annotation that an acceptable plasma substitute must be as innocuous and as effective as plasma itself. Because of its cheapness and ease of preparation, it can be of great value to doctors in those countries where there are no transfusion services.

Allergic Reactions to Penicillin

By A. I. SUCHECKI, M.D. (Paris)

(Abstracted from the *British Medical Journal*, 21st December, 1946, p. 938)

REPORTS on allergic reactions to penicillin are increasing in number. Evidence is accumulating that the offending agent is the active principle of penicillin.

Thirty-eight cases of allergic reactions to penicillin have been collected from the literature and reviewed.

Nine personal cases are added, of which 4 presented hydrarthrosis, 2 urticaria, and 3 serum-sickness-like reaction due to parenteral administration.

Local use of penicillin will give rise predominantly to contact or sensitization dermatitis, while parenteral administration will produce immediate or delayed reactions classed as (a) allergic hydrarthrosis, (b) urticaria, (c) simulating serum sickness, and (d) anaphylactic-shock-like syndrome.

The frequency of these reactions to parenteral penicillin has been put at varying figures between 0.56 per cent and 5.7 per cent. The former is probably nearer the truth.

So long as penicillin remains unsynthesized a categorical answer as to whether the reaction is due to impurities or active principle is impossible. The search for specific serum antibodies has so far given no convincing results. All that is known is that a small number of people are susceptible to penicillin sensitization, and that this susceptibility is greatly enhanced in the presence of skin infections, especially those due to a fungus. Previous penicillin treatment, parenteral or local, can predispose to allergic reactions. Some of these may be very severe and call for cessation of treatment; attempts at desensitization have been made by some workers. O'Donovan and Klorfajn successfully desensitized one of their patients by repeated oral doses of penicillin.

Skin tests have given variable results; the patch test is easy to perform and is frequently positive. Dr. P. Headon suggested dry powdered penicillin on a square of gauze applied to the skin of the chest or arms. In case 5 a positive result was obtained two hours after application, the patient complaining of itching in the right hand and swelling of the lips. The test was also positive in case 4, in which it was performed at the time of recovery; the same patient had a negative intradermal test. Adrenaline hydrochloride hypodermically and ephedrine orally gave rapid relief. These drugs should be repeated at frequent intervals in conjunction with small doses of phenobarbitone. 'Benadryl', the new anti-histamine drug, may be found useful in the treatment of manifestations of penicillin hypersensitivity, especially in cases with marked urticaria.

What should be done if penicillin is again indicated in a case with a history of extensive urticaria following previous penicillin treatment with subsequent recovery? Most observers are of the opinion that the drug should not be withheld if it is considered important to the treatment. The patient should be watched, and if an unusually severe reaction occurs, cessation of penicillin will have to be considered. No useful purpose is served by changing to another commercial batch. Dr. A. E. Shaw suggested the use of skin tests to discover susceptible individuals, especially

among those who have had (a) penicillin once or more previously; (b) a history of allergy, such as asthma, migraine, hay-fever; (c) fungus infection; (d) sensitization *eczemas*. Unfortunately skin tests are often negative in obviously allergic patients, and one wonders whether a preliminary injection of, say, 15,000 units, would produce a clear-cut and mild enough reaction to indicate a penicillin reactor.

Fatal Use of a Dangerous Universal Donor

(Abstracted from a letter written to the *Lancet*, 8th February, 1947, by DOUGLAS McRAE, Director, Blood Transfusion Service, Edinburgh and South-East Scotland Region)

It is to be hoped that all clinicians who order or give a blood transfusion will appreciate the importance of abhorring the use of the term 'universal donor'. As group-A and group-O people are, roughly speaking, numerically equal, if patients were grouped before transfusion, the demands for A and O blood could be made nearly equal; people of groups B and AB can of course be used to provide plasma. With donor panels decreasing in most regions, the urgent need for group-to-group transfusion cannot be too emphasized.

I think it is a pity to suggest that direct compatibility tests can be omitted even 'where urgency is too extreme to permit of such a test'. Surely the patient can and should be saved temporarily by the use of plasma until correctly matched blood is available. As an aid to routine compatibility tests in those patients who may require blood urgently (*e.g.* severe post-partum haemorrhage), it should be an automatic procedure that when a woman goes into labour, a specimen of her venous blood is withdrawn into a sterile tube. Her serum is then available for the direct compatibility test should she require blood.

Otic Complications of Streptomycin Therapy A Preliminary Report

By EDMUND P. FOWLER, Jr., M.D.

and

EWING SELIGMAN, M.D.

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, No. 2, 11th January, 1947, p. 87)

It is evident that a high incidence of vestibular disturbance and a number of cases of deafness, either transitory or permanent, will occur with the use of streptomycin of even the best current manufacture if large doses of the drug are given over prolonged periods.

It is hoped that it can be proved that the toxic symptoms are caused by impurities in the drug.

Fortunately patients seem to recover from deafness in the majority of cases, and even if the caloric response remains negative, the accessory balance mechanisms compensate marvellously for totally dead labyrinths, so that this need not be feared. In fact, the vertigo usually lessens even if the therapy is continued in spite of it.

The mechanism of the otic complications of streptomycin therapy is not clear. The cause could be either a labyrinthine or retrolabyrinthine lesion. Examination of pathologic material to date from the brains of dogs and human beings has failed to show any lesion attributable to streptomycin in the auditory tracts. Satisfactory temporal bone material is not yet available for study.

Eighty-one streptomycin-treated patients were examined for evidence of aural toxicity.

Two months after the cessation of therapy 3 of these patients showed an absence of vestibular response. During the third month after therapy 1 of these 3 has

shown increasing recovery of response. All 3 complained spontaneously of dizziness during treatment.

Another patient showed a severe loss of hearing two weeks after treatment. One month after treatment he had shown decided improvement in hearing. He had a normal vestibular response throughout.

The occurrence of otic symptoms during streptomycin therapy should call for a reconsideration of the case before continuing the administration of the drug. If streptomycin therapy is continued, the drug with another manufacturer's lot number should be tried.

An audiogram and vestibular test should be performed before the initiation of streptomycin therapy.

The low tone and high tone losses here reported are probably not due to streptomycin except in 2 cases. The low tone losses are probably due to outside interference. The losses in high-pitched tones relatively unimportant in the hearing of speech are the type commonly found in soldiers who have served in active combat.

Cancer Treatments from Russia

(Abstracted from the *Journal of the American Medical Association*, Vol. 133, No. 2, 11th January, 1947, p. 111)

THE KR treatment (*U.S.S.R. Information Bull.*, 6:2, Oct. 23, 1946) named after its originators Nina Klyucva and Georgi Roskin, is now being tested in the treatment of human cancer in Moscow, Russia, by Trutnev, Lyampert and Egorov. The method is said to have little effect in cancer of the skin but to show promise in cancer of the throat, uterine cervix and breast. The preparation is made from dead protozoa of the species *Trypanosoma cruzi*. The material is said to localize in tumours and destroy them. In a second release (*Ibid.*, 6:12, October 23, 1946) from the Russian Embassy there is a brief mention of another method said to be based on observations by Besredka. He found that a certain degree of immunity sometimes developed to transplanted tumours in animals when the transplants were made intracutaneously. Krashennnikov used the method in 2 cases of human gastric cancer and 2 in which the type of primary tumour is not stated. He excised 1 to 2 gm. of cancer tissue, wrapped it in a piece of omentum and transplanted it under the skin of the abdomen. It is stated that the transplant resolved promptly, as did also the primary tumour. It was believed that the transplanted cancer played the rôle of an autovaccine. The function of the omentum, presumably, was to supply cells for the fabrication of immune bodies.

Hedblom's Syndrome

(Abstracted from the *Medical Press*, No: 5613, 4th December, 1946, p. 414, under Current Topics)

THAT many of the symptom-complexes met with in everyday practice are 'missing' from the orthodox treatises on systematic medicine is a commonplace to the family practitioner.

Recently the writer has encountered three cases of 'acute primary diaphragmatitis'. The clinical picture, as described, includes inspiratory pain (ponopnea) on the affected side, limitation of mobility of the lower chest wall, and a tendency to a flaring out of the lower costal margin with each inspiration. Pain in the right or left upper quadrant of the abdomen with associated muscle spasm may be found. Pain in the homolateral shoulder and the trapezoid ridge may be complained of by the patient. X-ray appearances show a tendency to raising of the involved diaphragmatic leaf; mobility may be diminished or absent. The severity of these symptoms is variable. Treatment has been primarily symptomatic. Sedatives and

physical therapy have been employed. Opiates may be necessary to relieve the intense pain.

The disease is self-limited, but may have a tendency to recur. The attacks may follow a 'cold' coming on with a change in atmospheric temperature.

Cheese Rash

(Abstracted from the *Medical Press*, No. 5613, 4th December, 1946, p. 414, under Current Topics)

AFTER treating a man for corneal ulceration and a diplococcus infection by penicillin instillations, it was found that he developed a severe reaction. Penicillin ointment was then substituted; again he had a definite reaction. Two injections of 15,000 units of penicillin provoked a severe generalized rash over the body.

A month later he ate Roquefort cheese containing some of the mould. He developed the same kind of rash.

Some of the moulds in Roquefort cheese belong to the penicillin group, but since penicillin is a product of the metabolism of the mould, it is not known whether there are cross reactions between penicillin and the mould itself. The case recorded may have been an example of penicillin activity by mouth.

Drowsiness from Benadryl

(From the *Lancet*, ii, 30th November, 1946, p. 800)

THE drug 'Benadryl' (B-dimethylaminoethyl benzhydryl ether hydrochloride) has anti-allergic properties and also an anti-histamine action which enables it to relieve spasm of smooth muscle. It is given by mouth in capsules of 50 mg., the average adult dose being one to four capsules daily. It has been used with great success in urticaria, angioneurotic oedema, erythema multiforme, and hay fever; and Wilcox has shown that the urticaria which occasionally follows penicillin therapy also responds well. It is not, however, without toxic effects, the most prominent being drowsiness; and Slater and Francis describe a case in which an accident resulted from this symptom. A hay-fever patient took a 50 mg. capsule of benadryl at 7 a.m. and complained of feeling drowsy on starting work at 8 a.m. An hour later, while driving an electric platform cargo truck, he lost control and jumped off the truck. He was not hurt, but the truck ran off the platform and was wrecked.

More than half the patients taking benadryl notice slight drowsiness, and a few sleep for anything up to 18 hours at night, though this effect usually wears off in a day or two. When drowsiness is severe the dose may be reduced to 10-20 mg. A possible alternative would be to give amphetamine ('Benzedrine') in doses of 5 or 10 mg. at the same time. In the treatment of epilepsy it has been found that large doses of phenobarbitone (e.g. gr. 3 daily), which alone produce intolerable drowsiness, will still have the same effect on the fits if given in conjunction with amphetamine, though their hypnotic action is much reduced.

Mepacrine Rashes

(Abstracted from the *British Medical Journal*, ii, 14th December, 1946, p. 907)

DURING the recent war a number of puzzling dermatological problems arose in those theatres where mepacrine was employed in the prophylaxis or treatment of malaria.

The syndrome has certain distinctive features, among which are the pigmentation and lichenoid changes. It tends to affect seborrhœic sites, but readily progresses to a general affection, with secondary sepsis and ulceration, and it runs a protracted course. Irritation is not

a marked feature of the condition. It includes the following three types of reaction, and though all stages may be seen in the same patient, the lichenoid and generalized eruptions commonly follow the patchy eczematoid. (1) The patchy eczematoid type accounts for 30 to 40 per cent of cases; the hands and feet, groins, eyes and ears are the sites of election. (2) The hypertrophic lichenoid type may arise as such primarily but usually follows the former type. Spread is rapid, and the appearances resemble a very severe and unusually extensive chronic hypertrophic lichen planus. Mucous membranes are involved, as are the scalp and the face. The latter is rarely attacked in true lichen planus. A peculiar bluish-grey pigmentation occurs. The typical polygonal papules with flat, shining surface are absent, and the glans penis is not affected. (3) The generalized exfoliative type usually follows upon the eczematoid or lichenoid. If it is a primary occurrence it may be acute and oedematous and cause pyrexia.

The patients are ill and unfit for duty, are in hospital for an average period of three and a half months after being evacuated from the tropics, and may not recover for six to twelve months. Pigmentation may be very persistent and in some cases a fine reticular atrophy is seen. Hair and nails were often shed, but they grew again in all cases observed. No drug therapy proved of value except penicillin for the secondary sepsis that was a frequent complication.

The incidence of this adverse response to mepacrine was not sufficiently high to justify withdrawal of the drug from general use, but those subject to the disturbance, could not subsequently take the drug without relapse of the dermatosis. They had therefore to be withdrawn from those areas where prophylactic measures against malaria were necessary.

Tropical Ulcer Healing Under Lead Foil

(Abstracted from a correspondence written by H. M. FISHER, L.D.S., the *East African Medical Journal*, Vol. XXIII, No. 12, December 1946, p. 393)

It has been suggested by Dr. H. M. Fisher, L.D.S., that tropical ulcers like veldt sores and abrasions do not heal due to exposure of the ordinary dressed wound to the sun's rays and he suggested the trial of using a layer of lead foil between the dressing on the wound and the elastoplast holding it in position.

A. B. R. C.

Chemotherapy of Virus Diseases

(Abstracted from a letter from M. H. GORDON published in the *British Medical Journal*, 15th February, 1947, p. 266)

THE writer agrees with Dr. W. N. Leak's letter (25th January, p. 160) protesting against the statement in the leading article of 7th December, 1946, that there is scarcely a hint that viruses are susceptible to chemotherapeutic attack. In the case of both vaccinia and smallpox viruses there is definite evidence that they are extremely susceptible to the action of potassium permanganate, which inactivates them even when diluted to 1:100,000. This was described and illustrated in the Medical Research Council's Special Report, Series No. 98, 1925. During an outbreak of severe smallpox in the Sudan the cases had been treated with compresses soaked in permanganate and applied to the skin lesions with amazingly successful result. Balfour saw at the time that something more than to counteract any secondary infection must be involved to account for the beneficial effect. When he read the report in question and realized the high degree of susceptibility of smallpox virus itself to permanganate, Balfour was more delighted than the writer ever remembers to have seen him. The pronounced viricidal action of permanganate on vaccinia virus *in vitro* ceases in the presence of glycerine. The well-established

value of glycerine in conserving viruses is due to the protection it affords at their weakest point—hypersensitivity to oxidation. Bacteria are far more resistant to permanganate than viruses.

Wood's Light Fluorescence Phenomenon in Quinacrine Medication

By J. E. GINSBERG

and

P. L. SHALLENBERGER

(Abstracted from the *Journal of the American Medical Association*, Vol. 131, 6th July, 1946, p. 803)

As the result of the extensive use of quinacrine hydrochloride (atabrine) as an antimalarial drug during the war, its pharmacologic properties have become well known and have been discussed thoroughly in the literature. Temporary yellow discoloration of the skin and certain types of associated skin reaction, including bluish pigmentation of the nails and palate, due to the prolonged use of atabrine as an antimalarial prophylactic, have also been reported and observed by army physicians.

It is well known that atabrine when given orally accumulates in the tissues and is slowly excreted from the body. When its use is discontinued, excretion continues for long periods. Our present discussion shows that it is still present in the nails a year or more after regular oral ingestion of the drug has been stopped.

The present study was accidentally inspired by one of the authors (J. E. G.), who had recently spent almost two years as an army physician in the tropics) when he noticed a bright greenish yellow fluorescence of his own fingernails while examining a child for tinea capitis under Wood's light in his office. The other author (P. L. S.) had also noticed similar fluorescence to ultraviolet light while making a previous study of deposits of atabrine in the hard palate and fingernails.

OBSERVATIONS ON 511 GENERAL HOSPITAL PATIENTS OF ALL TYPES AND DEDUCTIONS

1. Patients still on atabrine antimalarial prophylaxis or those on atabrine therapy showed the characteristic greenish yellow fluorescence of all the nails under Wood's light all the way to the cuticle.

2. Those who had not taken atabrine for a month or more showed normal pearl white fluorescence in the proximal nail with greenish yellow fluorescence distally. The pearly white area corresponds to the nail growth in this period.

3. The proximal clearing was apparent in the fingernails before it appeared in the toenails after atabrine was discontinued.

4. Atabrine fluorescence tended to disappear entirely from the fingernails three to six months after the drug was stopped. In the hands, the nails of the thumb and forefinger tended to lose the fluorescence last. In the fingernails of one patient, however, the atabrine fluorescence was present in the nails of the ring fingers and toes only four months after discontinuing atabrine.

5. Atabrine fluorescence usually did not disappear from all nails until about one year after the drug was stopped. The great toenails frequently remain fluorescent several months longer than the others.

6. Studies of women's nails were in general unsatisfactory, because of staining from nail lacquer present or recently applied.

7. Subjects who had taken only small quantities of atabrine did not show the characteristic atabrine fluorescence phenomena.

8. Definite fluorescence of the nails was apparent in all subjects who were on atabrine therapy or sound prophylaxis when examined or who had discontinued using the drug within a six-month period.

Amyloid Macroglossia (Report of a Case)

By MARGARET D. BABER, M.D. (Lond.), M.R.C.P.
(Abstracted from the *Lancet*, 8th February, 1947, p. 210)

A CASE of association of macroglossia with amyloidosis was described. Patient, aged 63 years, gave a history of six weeks' dysphagia, the difficulty in swallowing being greater for solid than for liquid food, and giving an impression of food lodging in the throat. There was no pain. Radiography of the spine showed only senile osteoporosis of the vertebrae.

Physical examination showed a pale wasted dehydrated man. His speech was thick and indistinct, but his voice was not hoarse. His tongue was enlarged in all dimensions but did not fill the mouth completely. It was strikingly immobile, furred, and dry, and felt uniformly hard. No ulcer was seen.

The submaxillary glands were slightly enlarged but not hard, and there were several palpable glands of the same consistence in both anterior triangles of the neck. The sternomastoid muscles felt curiously indurated, but movements of the neck were not appreciably limited.

Laryngoscopy showed an oedematous type of swelling in the subglottic region, but no ulceration. Wassermann reaction negative. Radiography of the chest showed senile changes only.

A barium swallow suggested a filling defect in the upper end of the oesophagus.

After an unsuccessful attempt in introducing the oesophagoscope the patient died of coronary thrombosis as found in the necropsy. The whole tongue appeared to consist of pale homogeneous tissue, the cut surface of which, when stained with iodine, gave the mahogany colour typical of amyloid disease. The oesophagus formed a rigid tube, and its cut surface gave the same reaction with iodine. The other organs were not remarkable, except that the gall-bladder contained 'mixed' stones and inspissated pus. The liver, spleen, and kidneys appeared normal macroscopically.

The tongue, oesophagus, buccal mucosa, sternomastoid, and heart showed typical amyloid tissue, staining well with methyl violet. Apart from a few deposits of amyloid material in the glomerular tufts of the kidney, the liver, spleen and kidney were normal.

Amyloidosis with macroglossia appears to be a different condition from the classical form of amyloid disease due to protracted suppuration, tuberculosis, syphilis, Hodgkin's disease, etc. Unlike the latter, the amyloidosis has no predilection for liver, spleen, kidneys, and intestinal mucosa. On the contrary, these sites are completely spared or only slightly affected, and the main deposits are found in the tongue, skeletal muscles, and heart. Sometimes the skin, lungs and upper intestinal tract are involved also. None of the acknowledged causes of amyloid disease had been observed in cases of so-called atypical amyloidosis. In the case described the presence of pus in the gall-bladder was not likely to be relevant, since this is a fairly common lesion not recognized as associated with amyloidosis.

Unfortunately this case threw no light on the obscure aetiology of the condition.

A. B. R. C.

Distribution of Blood-Groups

(Abstracted from the *Lancet*, ii, 20th July, 1946, p. 94)

DURING the war G. L. Taylor and his co-workers examined the blood-groups of 190,000 people, mostly in the R.A.F., who were drawn from all over the United Kingdom. They also examined Belgian, Czechoslovak, Dutch, French, Polish, and Turkish—though the numbers were small. The findings have now been published by Dobson and Ikin. The distribution of blood-groups among the 190,000 R.A.F. men, which can be taken as representative of the distribution

for the United Kingdom, was : group O 46.7 per cent, group A 41.7 per cent, group B 8.6 per cent, and group AB 3.0 per cent. The incidence of abnormalities was very small. Thus cold agglutinins were detected in 61 persons, and in 15 cases (3 of group O, and 12 of group A) there was deficiency or complete absence of anti-B agglutinin; in only one case (group O) was anti-A agglutinin completely absent. These figures differ little from those already known, such as those recorded by the Hirzfelds in 1919 : group O 46.4 per cent, group A 43.4 per cent, group B 7.2 per cent, and group AB 3.0 per cent.

The findings in the small foreign samples are also in accordance with figures recorded by others, and show the characteristic fall in the frequencies of groups O and A and the rise in group B as one moves south and east across Europe; the Czechoslovaks clearly belong to the eastern European type. Of the inhabitants of southern Asia and Africa, 30-40 per cent are in group O, and group B is more common than group A; the Indians and Chinese are mostly similar, but over 10 per cent are in group AB. There is the curious 'Human' group of Chinese with a distribution like that found by Dobson and Ikin in their Czechs—i.e. group O 28.4 per cent, group A 46.2 per cent, group B 15.7 per cent, and group AB 9.7 per cent. The American Indians, both north and south, are remarkable for being nearly all group O. Within these large averages, smaller variations occur from place to place, as Dobson and Ikin illustrate with small samples from Cambridge and London. Their figures will form a firm basis for the assessment of blood available for transfusion.

Acute Infectious Lymphocytosis in England

By A. J. STEIGMAN

(Abstracted from the *Lancet*, ii, 28th December, 1946, p. 944)

A PAUCITY of clinical symptoms and a hyperlymphocytosis are characteristic of this communicable disease. No bacteria or viruses have been isolated, and Smith found an incubation period of 12-21 days. Biopsy of lymph-nodes shows a degeneration of the lymph follicles with proliferation of the reticulo-endothelium of the sinuses.

Most of the patients seen in the U.S.A. had no symptoms, the diagnosis being established on routine blood-counts in certain convalescent homes, orphanages, etc. The disease is almost entirely confined to children; those few with symptoms have had mild upper respiratory symptoms, low-grade pyrexia, cervical adenopathy, irritability, abdominal pain, and meningeal irritation.

Laboratory examination shows 12,000-100,000 leucocytes, with 50-90 per cent of small mature lymphocytes, and these findings may persist even up to several months. Bone-marrow smears show an increased percentage of small mature lymphocytes. No anaemia or thrombopenia develops, and the heterophil agglutination reaction is negative.

The differential diagnosis requires the exclusion of infectious mononucleosis (spleen, general adenopathy, angina, fever, atypical immature lymphocytes, and a positive heterophil agglutination); lymphocytic leukaemia (enlarged lymph-nodes and spleen, fever, lymphoblasts, development of anaemia and thrombopenia); and pertussis (clinical course and bacteriology).

The communicability of this disease is attested by the institutional outbreaks in the U.S.A., showing a high attack-rate. The exact mode of transmission is not known; treatment is symptomatic.

Three sporadic cases and a small outbreak of six cases were seen in 1942 in England. The sporadic cases, in common with the first American cases of Smith, had mild fever, malaise, fatigue, slight sore throat, and slight cervical adenopathy. The remaining six cases came from one village within a fortnight. The degree of cervical adenopathy was rather striking, but the

benign course, protracted lymphocytosis, and the absence of significant bacteria, anaemia, thrombopenia and heterophil antibodies were typical.

The recently recognized disease in children is probably not really new; probably institutional outbreaks, described as mild atypical forms of infectious mononucleosis, were really acute infectious lymphocytosis. Though the disease has been of special interest to paediatricians, there is no assurance of age limitation, just as there is no assurance of geographical limitation. All cases clinically detected so far have been very benign.

Diet and Canine Hysteria

By E. MELLANBY

(Abstracted from the *British Medical Journal*, ii, 14th December, 1946, p. 885)

THE practice of bleaching and improving flour by NCL, known as the agene process, is responsible for a flour which produces canine hysteria. The evidence is of a direct kind; the abnormality being produced by diets containing the treated flour, samples of the same flour untreated being harmless. Substitution of the treated flour by the untreated type tends to reverse the animal's condition and allows complete recovery from the hysteria and fits, even though the animal itself may not be normal. Recovery from the slighter but more chronic condition appears to bear a relationship to the length of time the animals have received the treated flour. If they have had it for a long period—e.g. six months—recovery may not be complete even after three to four months on the untreated flour, although the more severe abnormalities, such as hysterical and epileptiform fits, will cease within 24 to 48 hours of the change of diet.

It is agreed by experts in milling practice that the agene process affects the gluten of flour particularly. Chlorine can act energetically upon gluten, and the nature of the reaction includes the entrance of chlorine into such important parts of the gluten complex as the tyrosin and tryptophane groupings. These remarks upon chlorine apply also to nitrogen trichloride and evidence has been given that its action (i.e. that of NCL) on the protein of flour is probably similar to what we have already described in the case of chlorine.

The abnormal behaviour of the animals affected by the agenzized flour suggests that the central nervous system is primarily affected by some toxic agent, but other organs may also be involved. A few dogs have died in these attacks, but ordinary post-mortem examination has not yet revealed any lesion which can be regarded as the essential one. It is clear that investigations must now be made to see whether human beings are affected by bread made from flour improved by NCL.

Penicillin in the Treatment of Thiouracil Agranulocytosis

(Abstracted from the *British Medical Journal*, ii, 14th December, 1946, p. 899)

AGRANULOCYTOSIS may occur as a serious complication during treatment with methyl thiouracil. Reports in the American literature of the success of penicillin in this condition prompted its use in this case. It would seem that penicillin is a most convenient form of therapy for agranulocytosis.

A New Anti-Allergic Serum

(Abstracted from the *Current Science*, Vol. 15, September 1946, p. 248)

ALLERGIC reactions, which appear in man after injection of horse serum, are believed to be manifestations of antigen-antibody reactions.

Enzymic treatments of horse serum proteins appear to reduce their specific antigenicity. A large part of the immune bodies is, however, lost during enzymic treatment and subsequent processing.

The alternative method of preventing serum reactions by inactivating the antibody has given satisfactory results. For this purpose, anti-human serum is prepared in horses. Horses are injected intravenously every fifth day with pooled human serum of doses which gradually decrease from 250 ml. to 25 ml. The serum of such horses contains complement-fixing antibodies to human serum proteins, and inhibits appearance of serum reactions in man. Thus, the same serum, which contains the antigen which is responsible for the serum reactions, also contains the protective substance which inhibits serum reactions presumably by inactivating the antibody.

The anti-human serum has not shown any untoward effects in man. It is, therefore, quite safe to use this serum in man for the prevention or inhibition of allergic reactions.

Vitamin K in General Practice

By D. M. EVANS

(Abstracted from the *Practitioner*, Vol. 157, November 1946, p. 391)

SINCE the beginning of the recent war the writer has been greatly puzzled by slight but definite changes in the behaviour of certain diseases among his patients particularly regarding incidence and course and also the effectiveness of treatment.

He has found a wider age-incidence in such conditions as nasal catarrh, impetigo, fibrositis following mild infections; increased liability to recurrent 'colds' and increased incidence of such 'extension' conditions as conjunctivitis, Eustachian catarrh and otitis. The usual forms of treatment have seemed gradually to lose their effect and even more advanced methods have in turn seemed to become less effective of late. For instance, before the war impetigo in children was usually curable with little difficulty by the use of ammoniated mercury ointment and later by sulphonamide therapy. Now he finds that the sulphonamides, vaccines and even penicillin tend to take longer than at first to end the condition, with little guarantee against recurrence.

Such changes he has long suspected to be due to the lack of some factor, missing either from the changed diet or as a result of such change. By a coincidence, while using vitamin K analogue (acetomenaphthone) in the case of a nursing mother with a baby suffering from steatorrhea, he was led to believe that vitamin K might be the substance involved in the changes he had observed.

As a result of this case, he experimented further in cases of obvious toxemia due to various conditions and was frankly amazed by the results. However prejudiced he assumed himself to be and in spite of many arguments he put forward against the likelihood of their being directly attributable to the treatment prescribed. Acetomenaphthone he first used alone and found it markedly effective in the toxic stages of the illness treated, but later added nicotinic acid as a result of the observation that even with rapid recovery the patients either showed marked signs of deficiency of the latter vitamin or had recurrence of their original symptoms after apparent cure.

In some cases, such as impetigo and furunculosis, additional local or general treatment was necessary, although these latter were almost useless alone.

Many cases have been treated, including primary colds, chills, acute nasal catarrh, acute sinusitis, acute catarrhal bronchitis, influenza, and chronic tonsillar and dental sepsis.

He has also observed that in patients requiring morphine or its derivatives while being treated with acetomenaphthone, the expected nausea and malaise were absent.

The diversity of conditions which seem susceptible to treatment with vitamin K suggests that this vitamin

may have some importance in the mechanism of resistance to infection, possibly by facilitating detoxication. As prothrombin, an essential factor in the defence of the body, is synthesized by the liver with the aid of vitamin K, and since the liver, the chief detoxicating centre of the body, is responsible, by virtue of its secretion of bile salts, for the absorption of this vitamin, it seems likely that vitamin K might also be essential to the liver in that other phase of defence, namely, detoxication.

Conjoined Action of Penicillin and Bacteriophages

By W. J. MacNEAL, et al.

(Abstracted from the *Journal of Laboratory and Clinical Medicine*, Vol. 31, September 1946, p. 974)

CULTURES of staphylococcus moderately resistant to penicillin and to bacteriophages may be more effectively inhibited in their growth by a combination of these agents. Similar observations have been made on cultures of colon bacilli and some types of streptococci.

Severe types of infection with staphylococcus, such as chronic osteomyelitis, facial carbuncle, and staphylococcal endocarditis have responded to combined therapeutic use of penicillin and bacteriophages.

Intestinal perforation associated with general peritonitis and bacteremia has been successfully treated with coli bacteriophage and penicillin.

Bacterial endocarditis due to streptococci relatively resistant to penicillin has responded favourably to treatment with penicillin and suitable streptococcus bacteriophage.

Gargoylism

(Abstracted from the *Medical Journal of Australia*, Vol. I, 22nd June, 1946, p. 890)

A MALE child, aged fifteen months, with some of the features of *dysostosis multiplex* or gargoylism was shown. The child had been born at term and the confinement was normal. His birth weight was seven pounds and seven ounces. His mother suffered from a twisted ovarian cyst when she was five months pregnant, but this subsided with the administration of morphine. She had a number of small vaginal hæmorrhages from six months till term. She had suffered from no infectious disease. The baby sucked poorly and breast feeding could not be established. No trouble was experienced with artificial feeding. At first 'Lactogen' and later cow's milk mixtures were used.

The child was first seen when he was seven months old. The mother had observed some stiffness of the legs and hips and had commented on the fact that he had kept his fists clenched. She reported that he had been backward in development and made peculiar snorting noises. At seven months he weighed eighteen pounds six ounces, and his head circumference was eighteen and seven-eighths inches. The forehead was prominent. The breathing was snuffly, though no nasal discharge was present. The features were coarse and he was retarded mentally. There was limitation of movement at the elbows, fingers and knees. The cornea were not clouded. No localized kyphosis was present and the spleen was not palpable. Dr. Colin Macdonald had reported that the x-ray appearances were consistent with a diagnosis of *dysostosis multiplex*. There was thickening of the frontal bones, the supra-orbital ridges being wide and prominent. The calvarium presented a ground-glass appearance and the *sella turcica* was small. The ribs were thick and heavy. The vertebrae showed some degrees of platyspondylitis, but a hook on the anterior aspect of the twelfth thoracic or first lumbar vertebra could not be demonstrated. X-ray examination of the pelvis revealed

bilateral subluxation of the hips and *coxa valga*. The subluxation was poorly defined on each side. The femora were thicker than normal.

All the stigmata were not present, but sufficient evidence was present to justify his making a definite diagnosis and leaving it in the category of *forme fruste*. A comprehensive article on the subject with good illustrations could be studied in *The Quarterly Journal of Medicine*, 1936.

Löffler's Syndrome: Report of a Case with Pathologic-Examination of the Lungs

By E. C. BAILEY, *et al.*

(From the *Archives of Pathology*, Vol. 40, November-December 1945, p. 376, as abstracted in the *International Medical Digest*, Vol. 48, May 1946, p. 285)

THE post-mortem examination was limited to a study of the lungs. There were numerous adhesions between the visceral and the parietal pleura. Approximately 300 c.c. of serosanguineous fluid were present in each pleural cavity. The bronchi contained considerable tenacious mucosanguineous exudate.

Numerous irregular-shaped regions of increased density were scattered throughout both lungs. The pleura was thickened over these regions, and adhesions were frequently present. The cut section revealed these areas to be of varying size and shape. The largest measured roughly 5.0 cm. in its greatest extent, while the smallest were only a few millimetres in diameter. Some of the latter resembled tubercles. The nodular regions were greyish-yellow and firm to palpation, and no exudate could be expressed from them. In the lower lobes there were larger, dark red, consolidated regions at the bases which exuded serum and blood. The bronchi contained mucus, and the walls of some of them were greatly thickened. The alveoli appeared dilated, especially in the upper lobes. Portions of the nodular and the consolidated regions were removed with sterile instruments and referred . . . for culture and guinea-pig inoculation with a view to the possible presence of *Mycobacterium tuberculosis*. The results were reported as negative.

Sections taken from the firm, scarlike regions revealed extensive replacement of the normal parenchyma of the lung by masses of fibroblasts and collagenous fibres. In the meshes of the latter were large numbers of eosinophilic leukocytes, plasma cells, lymphocytes and some giant cells. These cells were found in focal collections and also diffusely distributed throughout the new connective tissue. The appearance was that of an unusual form of organized pneumonia in which there was an abnormally large number of eosinophilic leukocytes. In some portions of the pneumonic process there was also focal, tubercle-like lesions. The centres of these lesions consisted of acidophilic granular necrotic material. Mononuclear cells and fibroblasts could sometimes be observed in between the clumps of acidophilic granular necrotic debris. Eosinophilic granules could be detected in the clumps of granular material. Large histiocytes, epithelioid cells and fibroblasts surrounded the central portion of the

lesion. These cells were usually arranged radially. An outer zone of eosinophilic leukocytes, plasma cells and lymphocytes was present. Multinucleated giant cells of variable shape and nuclear arrangement were observed occasionally in the tubercle-like lesions. The latter did not have the typical appearance of the tubercles of tuberculosis. A superficial resemblance to the granulomatous lesion of rheumatic fever was discernible. The walls of the arteries and arterioles were moderately thickened. The capillaries were dilated, and hemorrhages were common. There was a severe periarterial and pericapillary inflammatory process in which eosinophilic leukocytes and plasma cells were the principal cellular elements. Actual necrosis of the arterial and venous walls was occasionally observed. In the region surrounding the organized pneumonia the alveolar walls were much thickened by a cellular exudate consisting largely of eosinophilic leukocytes, plasma cells and lymphocytes. This portion had the appearance of interstitial pneumonia. Moderate emphysema was present.

In sections of the lower lobes a more recent inflammatory process was evident. The alveoli contained serum, red cells and fibrin in addition to the cellular elements observed in the upper lobe. Large phagocytic cells were numerous and were found to contain vacuoles and pigment. Beginning organization of intra-alveolar fibrin was occasionally observed. The same vascular changes were observed as were present in the upper lobe. The tubercle-like lesions were frequently present. The bronchioles were filled with mucus and desquamated epithelial cells. Thickening and hyalinization of the basement membrane were prominent. There was no evidence of hypertrophy of the musculature but the walls were infiltrated with eosinophilic leukocytes and plasma cells. Interstitial pneumonia was also present in some regions. Moderate to severe emphysema was observed. Arteriolar sclerosis was graded 3 (on the basis of 1 to 4, in which 1 designates the least and 4 the greatest amount of sclerosis).

Sections of the upper and the lower lobes were appropriately stained for bacilli of tuberculosis, but no organisms could be found. No micro-organisms could be detected in sections stained by the Brown-Gram method.

Treatment of Ulcerative Colitis with Thiouracil

By L. MARTIN

(Abstracted from the *Lancet*, ii, 28th December, 1946, p. 914)

ADMINISTRATION of thiouracil in three cases, and methyl thiouracil in one case, of ulcerative colitis in relapse was followed by immediate improvement.

Hypothyroidism was not induced.

Further trials are needed to determine the necessary duration of treatment and to detect any effect on the natural course of the disease.

Thiouracil is chemically similar to synthetic 5-methyl uracil, which is effective in treatment of the anaemia and diarrhoea of tropical sprue.

Reviews

TEXTBOOK OF MEDICINE.—By various authors: Edited by Sir John Conybeare, K.B.E., M.C., D.M. (Oxon.), F.R.C.P. Eighth Edition. 1946. E. and S. Livingstone Limited, Edinburgh. Pp. xx plus 1170. Illustrated. Price, 30s.; postage 9d. (Home)

THIS well-known and popular book has now reached its eighth edition, the first edition having been published in 1929. Of the shorter textbooks of medicine it is one of the best and has proved to be of great value to the student beginning his clinical career.

In most sections of this edition there have been only minor alterations. Some of the articles on tropical diseases have been rewritten. New additions include sections on menopause, penicillin therapy and aviation medicine as well as a table of physiological normals on the inside of the front cover for ease of reference. Each chapter appears to be a masterpiece of conciseness and clarity. The book is recommended to all students.

HAEMORRHOIDS

The immediate relief of irritation

Anusol Haemorrhoidal Ointment can be confidently applied in cases where local inflammation of the anal regions is present. This preparation, because of its soothing, emollient and haemostatic effect, also relieves the pain

and discomfort caused by haemorrhoids. Anusol Ointment does not contain narcotics, analgesic or local anaesthetic drugs, and therefore does not mask the symptoms, and improvement is genuine.

Martin & Harris Ltd.,

Asthenia

The incidence of asthenia and malnutrition demands a preparation of proved tonic powers which is admirably provided in Waterbury's Compound. The intake of this preparation, which contains as its components products obtained by the enzymatic action of pancreatic ferments on cod liver oil, livers and spleens, malt extract and hypophosphites, results in the stimulation of physical vigour and disappearance of the signs of inanition. Waterbury's Compound is agreeable to the palate and is suitable for administration to patients of all ages.

Also at Bombay, Madras and Karachi.

Made by Waterbury Chemical Co., Inc., New York and St. Louis, U.S.A.

WATERBURY'S COMPOUND

Effective and Low Dosage Sulphonamide Therapy
with

IRGAFEN

(N,3, 4-Dimethylbenzoyl Sulphanilamide)

A well tolerated chemotherapeutic agent with definite action.
Total dosage 30-50% lower than that of other sulphonamides.

Indications :

Pneumonia, meningitis, B. coli infections, strepto- and staphylococcal infections, dysenteric enterocolitis, etc.

Tablets — Ampoules

J. R. GEIGY, S.A., BASLE
(SWITZERLAND)

For detailed literature please write to :

Amalgamated Chemicals and Dyestuffs Company Limited, P. O. Box 965, Bombay.

VITAPHOR

**indicated in all cases of
VITAMIN DEFICIENCY**

VITAPHOR—the perfect TONIC is standardised to contain the following active Vitamins in each fluid ounce :

B₁ 450 International Units
C 1300 International Units
D₂ 1650 International Units

Without these essential vitamins normal health cannot be maintained. Vitaphor also contains the Glycerophosphate of Sodium, Potassium, Strychnine and Magnesium all combined in a suitable base which gives to this Tonic a pleasant and agreeable taste. Prescribe Vitaphor in all cases of Convalescence from acute illness in cases of undevelopment, faulty Nutrition and all "run down" conditions when the body is in a low state of health.

SMITH STANISTREET & CO. LTD.

CALCUTTA BOMBAY MADRAS KARACHI AMRITSAR LUCKNOW

PULMONARY TUBERCULOSIS: A HANDBOOK FOR STUDENTS AND PRACTITIONERS.—By R. Y. Keers, M.D., M.R.C.P. (Edin.), F.R.F.P.S. (Glas.), and B. G. Rigden, M.R.C.S. (Eng.), L.R.C.P. (Lond.). 1946. E. and S. Livingstone Limited, Edinburgh. Pp. xvi plus 277. Illustrated. Price, 17s. 6d.; postage, 7d. (Home)

IN this new edition the book has been revised and partly rewritten, and includes some recent advances on the subject. The sections dealing with pneumoperitoneum and B.C.G. vaccines have been expanded. The number of illustrations has not been altered but some new x-ray photographs have been substituted. Each is accompanied by line drawings with legends. Here the student will find that when he comes to put his knowledge into practice he will be amply repaid for the time spent in their study. As a concise up-to-date account of pulmonary tuberculosis this handbook ought to be welcomed not only by medical students but also by general practitioners.

R. N. C.

GLOBAL EPIDEMIOLOGY: A GEOGRAPHY OF DISEASE AND SANITATION.—By James Stevens Simmons, B.S., M.D., Ph.D., Dr.P.H., Sc.D. (Hon.), Tom F. Whayne, A.B., M.D., Gaylord West Anderson, A.B., M.D., Dr.P.H., Harold Maciachlan Horack, B.S., M.D., and Collaborators. Volume I. Part I:—India and the Far East. Part II:—The Pacific Area. 1944. William Heinemann (Medical Books) Ltd., London. Pp. xxvi plus 504. Illustrated. Price, 30s.

GLOBAL EPIDEMIOLOGY produced by the U.S.A. Government Agencies, in response to urgent military requirements during the war, displays the thoroughness of scientific planning which characterized all U.S.A. war endeavours. It is an admirable guide book for a foreigner interested in the health problems of India and the Far Eastern countries some of which are more or less a closed book to most people. The reader will find an account of the public health and medical relief set up of the country, facilities for the production of drugs and biological products, a short account of the principal diseases prevailing in the area, of the insect vectors—actual and potential—and of other harmful agencies. It also deals with environmental sanitation. Certain instructions are given for the benefit of the non-technical new-comer.

An important point brought out by the surveys of different countries is, as the authors tersely put it, that the only permissible generalization is to state that generalization is impossible. Each country or part of country is a problem by itself in regard to a given disease and any one who aims at solving these problems without a thorough objective study is doomed to disappointment. The man, society and environment vary, and so also the host-parasite relationship and its manifestations. This complex mechanism of epidemiological happenings is further complicated by ecological differences in insects and other intermediary hosts. To quote a well-known instance, the diversity of breeding habits of malaria-carrying species of mosquitoes entirely changes the problem of malaria control from place to place. To take another instance in New Mehrides, *A. aegypti*, which is a day-biter elsewhere, changes its habit to night biting when it gets older.

Many less-open countries are free from certain diseases at present but in this age of shrinkage of the globe due to the annihilation of distance there is danger of these countries being laid open to exogenous diseases to which the indigenous population is non-immune. They are threatened with a grave situation unless our World Health Organization takes advance measures for their security. This point has been fully illustrated. However, a careful perusal of the work will also make one wonder why with all available facilities certain diseases have not acquired a much wider distribution. This suggests much deeper studies than the survey reported here.

The authors rightly claim that besides serving an important, though temporary purpose during the war, these studies should be of considerable value in peace time. It is a war legacy of the desired type. This purpose would be best served if an agency like the World Health Organization could continue the observations and keep the records up to date.

Since a large volume of scattered literature has been put together much data, which would otherwise be unavailable to workers in different countries, has been made accessible. Thus comparative epidemiology may yield useful results. However, it would be a mistake to think that the surveys recorded in this book are detailed enough for the formulation of public health schemes and programme for the countries' concerned as much more detailed studies of man, society and environment are necessary for the purpose. The name selected is a happy one. It emphasizes two important features of public health, viz, the large scope for beneficent human relationship and the growing intimacy and interdependence of different countries of the world.

R. B. L.

DISEASES OF THE NERVOUS SYSTEM DESCRIBED FOR PRACTITIONERS AND STUDENTS.—By F. M. R. Walshe, M.D., D.Sc., F.R.C.P. (Lond.), F.R.S., D.Sc. (Hon.), Nat. Univ., Ireland. Fifth Edition. 1947. E. and S. Livingstone Limited, Edinburgh. Pp. xvi plus 351. Illustrated. Price, 16s.; postage, 7d. (Home)

THIS comparatively new book, first published in 1940, has already become an old friend. The present edition is the fifth. In between editions it has been reprinted three times.

Written for practitioners and students the book excels in clarity and brevity. Complicated details of doubtful histology which demoralize students and bore practitioners have been kept out.

The subject is well covered: one could have said fully covered if one were not aware of omission of some diseases (*Myotonia congenita*, for instance) described by the author, as a contributor, in a textbook of medicine.

The lack of enthusiasm in penicillin in the treatment of early dementia paralytica (p. 174) does not appear to be in keeping with the recent American reports.

S. D. S. G.

AN INTRODUCTION TO SOCIAL BIOLOGY.—By Alan Dale, B.Sc. 1946. William Heinemann (Medical Books) Limited, London. Pp. vii plus 396. Illustrated. Price, 15s.

THIS interesting book will probably be recast in the next edition with a view to separating the basic sciences a little. At present one finds the face view of a German wasp almost next to a geological table.

A few clarifications are also indicated. In *Man And Evolution*, for instance, one does not know whether by sub-man is meant a sub-Homo or a sub-sapiens species. It may not be possible to decide: Heidelberg man is known both as Homo heidelbergensis and Paleoanthropus heidelbergensis. The fact, however, should be stated, as can be done easily by giving the full zoological names to the species mentioned.

The chapters on *Man As An Animal* and *Maintaining the Human Species* are presented particularly well and include a very good account of genetics.

Space has been found in the last two pages for the obfuscation of 'Holism' (wholeness). 'The theory of Holism postulates a fundamental principle or tendency leading to the production of wholes, a creative tendency which causes the appearance of new wholes at successively higher levels'. Thus do biologists turn metaphysicists!

A very good attempt at popularizing biology. It is hoped that the size of the book will not increase in the future editions.

S. D. S. G.

THE RHESUS FACTOR.—By G. Fulton Roberts, M.A., M.B. (Cantab.). 1947. William Heinemann (Medical Books) Limited, London. Pp. 47. Price, 3s. 6d.

In this little pamphlet the author has aimed at giving the barest skeleton of the Rhesus Factor. He has succeeded.

Even case reports and treatment have been included and so has been an unorthodoxy in immunology that 'the first few drops of a transfusion could, so sensitize the patient that the next few drops could produce a reaction'. This of course is not only 'exceptionally rare' but simply does not occur.

The pamphlet consisting of 30 small leaves of straight-forward printing, without a binding, is priced at 3s. 6d. The price appears to be excessive.

Abstracts from Reports

ANNUAL REPORT OF THE WORKING OF THE CIVIL HOSPITALS AND DISPENSARIES IN THE PROVINCE OF ASSAM FOR THE YEAR 1944 WITH BRIEF EXPLANATORY NOTES. BY COLONEL S. L. BHATIA, M.C., M.D., F.R.C.P., C.I.E., I.M.S., INSPECTOR-GENERAL OF CIVIL HOSPITALS, ASSAM. PRINTED AT THE ASSAM GOVERNMENT PRESS, SHILLONG. PRICE, Rs. 4-12 or 7s.

The year opened with 325 hospitals and dispensaries of all classes and closed with 332 as against 288 (excluding those in the Naga Hills and Manipur) in 1943. This increase was due to the provision of two State Public, five State Special, one local fund and five Government subsidized dispensaries.

The total number of in-door and out-door patients treated at medical institutions increased from 1,468,390 in the previous year to 1,658,557. The increase was confined to the districts of Cachar, Sylhet, Khasi and Jaintia Hills, Lakhimpur, Goalpara, Darrang, Nowgong and Garo Hills. In other districts there was decreased attendance. The increase was ascribed to the high incidence of malaria in the rural areas particularly in the village of Baniyachong of the Sylhet district and also to the increased population.

The total number of beds provided in all classes of hospitals increased from 1,469 in 1943 to 1,997 in the year under report.

During the year under report, no important improvements to the State and Local Fund institutions were carried out from public philanthropy.

The major project which was carried out during the year was the sinking of 6 tube-wells in the compound

of the Tezpur Mental Hospital at an estimated cost of Rs. 31,536.

Venereal diseases.—The total number of patients treated for gonococcal infections was 2,395 against 2,130 in 1943. Syphilis cases treated rose from 1,103 in 1943 to 1,506 in 1944.

Cholera.—Six hundred and ninety-five patients were treated in 1944, against 4,112 in 1943.

Malaria.—The total number of cases treated was 801,577 with 296 deaths against 553,361 with 260 deaths in the previous year. The chief increase was confined to the districts of Sylhet, Khasi and Jaintia Hills, Goalpara and Darrang. The Assam Medical Research Society continued to confine itself to study malaria and its control during the year, but there was a great set-back in the activities of the Society due to the curtailment of staff.

Kala-azar.—The total number of cases treated in 1944 in dispensaries other than those directly under the Public Health Department was 5,400 against 6,163 in 1943.

Leprosy.—The leper asylums, colonies and wards continued to do valuable work during the year. Three batches of rural health inspectors under the Public Health Department were given short lecture demonstrations in the Sylhet Leper Asylum on the diagnosis of leprosy. Propaganda work with the aid of magic lantern demonstration and by means of distribution of leaflets at Government expense was continued.

Tuberculosis.—Anti-tuberculosis propaganda was carried out as in the previous year. Accommodation at the Chest Clinic Hospital at Shillong has risen from 28 to 47 during the year. Further, the Bejoyendra Clinic opened at Dibrugarh in 1944 was doing good work.

Yaws.—The total number of cases treated in dispensaries and hospitals was 375 in 1944 against 460 in 1943. The campaign against yaws was continued during this year.

The total number of subsidized dispensaries functioning at the end of the year was 13. The number of patients treated increased from 17,225 in 1943 to 31,499 in 1944.

The scheme for the re-organization of the nursing services in Assam is under consideration of Government. The trained nursing sisters in Dibrugarh, Sylhet and Gauhati continued their excellent works.

Two large hospitals at Lekhapani and Saltspring were established during the year under report to provide medical facilities to the large number of porters engaged in connection with war in the Assam Frontier Area.

The dispensaries at Badarpur, Barpeta, Gauhati and Mariani established in 1944 rendered valuable service to the police staff of the Railway Security Police Organization.

A sum of Rs. 26,000 was sanctioned to the Blood Transfusion Service in Assam. The Blood Transfusion Officer was given training at Calcutta and Bombay. This organization did good work during the year.

Anti-malarial work and anti-infection measures were carried out by the civil medical authorities in and around aerodromes in Assam during the year under review.

SIXTEENTH ANNUAL REPORT OF THE ASSOCIATION FOR THE PREVENTION OF BLINDNESS, BENGAL, FOR THE YEAR 1945-46

Research.—Captain E. J. Somerset, I.M.S., one of the joint honorary secretaries of the Association, has been appointed by the Indian Research Fund Association, a member of the Clinical Research Advisory Committee. A research on the causes of blindness has been sanctioned and is in progress at the Eye Infirmary, Medical College, Calcutta. So far 1,400 cases has been investigated.

Enumeration of the blind.—The number of blind counted in the villages of Bengal has been recorded

according to age, sex, occupation and probable causes of blindness. Out of a total population of 68,749 in 113 villages counted during the year 121 persons were found completely blind. The probable causes of blindness were cataract, smallpox, glaucoma, couching, corneal ulcer, keratomalacia, etc.

Propaganda.—Preventive activity of the Association was carried out with the help of magic lantern slides, posters, movies, etc. Lectures and demonstrations were given in schools, colleges, associations, orphanages, exhibitions, etc.

Routine work.—There are at present five travelling eye dispensaries at work in Bengal, which treated 58,024 cases during the year. One thousand nine hundred and twenty operations were performed, including 589 for extraction of lens. The eye examination and lecture unit in Calcutta has carried out 3,636 eye examinations which shows various defects of which the most important are conjunctivitis, myopia and leucoma (probably result of corneal ulcer).

General.—More funds are essentially required, and the Committee are anxious that their activities should not be curtailed for inadequate money. The Committee hope that the Government and the public will continue to give their support so that these five travelling dispensaries may continue to serve permanently.

Mr. L. R. Fawcus, I.C.S., President of the Association, is retiring and will be succeeded by Mr. Justice C. C. Biswas.

R. N. C.

Correspondence

MEDICAL TREATMENT OF INTESTINAL OBSTRUCTION

Sir,—The article on 'Medical Treatment of Intestinal Obstruction' published on page 10 of January 1947 issue of the *Indian Medical Gazette* is capable of wrong conceptions. Allow me therefore to make a few comments:

1. (a) Mortality of 40 to 80 per cent refers to cases where medical treatment has failed.

(b) Question of operative treatment by those having neither facilities nor experience is nowhere contemplated.

(c) Hospitals usually get late cases, even moribund cases.

It is therefore I say that I would risk my reputation and recommend operation no sooner diagnosis is firmly established rather than wait on the off-chance of obstruction clearing itself or volvulus untwisting itself by the injection treatment. I personally believe that even in a doubtful case risk of laparotomy is a hundred times less than leaving a case of obstruction for a few hours.

When a patient point blank refuses operation then any treatment is good enough. I mean physostigmine, gynergen or even pituitrin, atropine, eserine, etc. The justification for an opinion in favour of author's treatment as against a laparotomy is untenable.

2. A practical suggestion about the level of obstruction, i.e. large or small intestine, might be helpful. In small gut obstruction vomiting is early and distension more a suggestive fullness, whereas in large gut, vomiting is a late phenomenon while abdominal distension an early occurrence.

3. First enema is of little importance. It is only the second enema which matters, i.e. if results of this are disappointing, i.e. no faeces, above all no flatus.

4. The author makes no mention of gastric aspiration and lavage the benefits of which are numerous.

TRICHINOPOLY.

P. V. KARAMCHANDANI,
LIEUTENANT-COLONEL, I.M.S.,
District Medical Officer.

Any Questions

DEGREES IN PHARMACY

SIR,—I am a qualified Government apothecary of 17 years of service in the medical department of Ceylon. I am anxious to study further to obtain the diploma or degree of M.P.S.—Member of the Pharmaceutical Society, England. But owing to financial difficulties I am unable to proceed to England.

I understand there are institutions now in India where necessary tuition is given for similar diplomas or degrees. If such are available please let me know the names and addresses of the institutions or schools as early as possible.

Yours, etc.,

B. C. A. KADIPPILY.

GOVERNMENT DISPENSARY,
RANNA (CEYLON).

[There is no institution in India where a diploma of M.P.S. (Lond.), Ph.C., or B.Pharm. (Lond.) is offered. You can get these only by undertaking a course of study and practical training at the Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, London, or any institutions affiliated to that body.]

The degree of B.Pharm. or B.Sc. Pharm. is being offered at the Benares Hindu University, Andhra University, the Madras University, the Bombay University and the Punjab University. The minimum basic qualification required for entrance to these courses is Intermediate in Science with Chemistry, Physics and Biology or Mathematics as the main subjects. The Madras University course is a two-year one, whereas in all other places a three-year course is enjoined. In the Andhra University, the degree is offered under the Technology Faculty.

If you have passed an examination similar in standard to I.Sc. prior to your qualification as an apothecary, it might be possible for you to gain admission in one of the institutions referred to above. You have to be a Matriculate of London University to get admission into the pharmaceutical courses in London University. An apothecary not having the minimum basic qualifications mentioned above is usually not admitted into the courses leading to M.P.S. diploma in London or to one of the degree courses either in India or U.K.

Reference may be made to *Indian Journal of Pharmacy*, Pharmacy Number, vol. 6, 1945, pp. 47-48, for further particulars. Copies of the journal can be had from the Benares Hindu University, Benares.—B. M.]

STORAGE OF PENICILLIN

SIR,—With reference to Dr. Rajendra Singh's letter which appeared in your issue for December 1946 regarding 'Storage of Penicillin' the following extracts from a circular note issued by Messrs. H. J. Foster and Co., Bombay, dated 4th February, 1947, appear in conflict with the writer's recommendation to keep penicillin in either refrigerators or ice-boxes.

'It is now known that the stability of solid penicillin of this degree of purity (84-93 per cent) is more dependent on the exclusion of moisture than upon any other single factor. Storage at 100°F. does not by itself destroy penicillin "Glaxo".

Samples of penicillin "Glaxo" kept at ordinary room temperature in Bombay and re-assayed by Glaxo Laboratories Ltd. at intervals extending over six months after manufacturing date have shown no appreciable loss of potency.

Do not keep penicillin in a vacuum flask containing ice or in an ice-box in which the containers are in actual contact with the ice. It is much preferable to keep it dry at room temperature, for even the best

of rubber-capped containers will not exclude moisture indefinitely if kept under damp conditions.

It would be interesting to know what the effect on potency of penicillin would be if stored under the ideally dry conditions stipulated but exposed to the very high temperature obtaining in the plains in the hot weather, say anything up to 120°F.

Yours faithfully,

B. J. BOUCHE, M.B.C.S., L.M.C.P.,
MAJOR, I.M.D. (retd.).

P.S.—From the foregoing it would appear that cold storage in hill stations is unnecessary. How long would it be considered safe for the solution to be kept in cold storage or otherwise once it has been made up? The latest reviews on penicillin are silent on these points.

[*Penicillin powder*.—Both temperature and moisture—individually and collectively—have an effect on the rate of deterioration of penicillin. The 'brand' of penicillin and the type of stoppers and seal employed are also important.

That temperature alone has an effect on the rate of deterioration is evident from the progressive loss of activity of penicillin, even when it is contained in flame-sealed all-glass ampoules. At 80°C. there is usually no loss of potency, whereas at 56°C. there is always a certain amount of loss of activity. It has been reported that certain samples of 85 to 93 per cent degree of purity remain stable up to 6 months at 37°C. Crystalline penicillin sodium kept for 1 month at 56°C. does not show any detectable loss of activity.

It is quite possible therefore to have a preparation of penicillin which will remain stable up to 6 months at ordinary temperature.

The effect of moisture on the activity of penicillin is usually most evident in rubber-stoppered aluminium-sealed vials, which may absorb moisture. The loss of activity in these vials usually increases progressively in the range of high temperatures. Moisture uptake up to 2.5 per cent does not result in much loss of potency in 3 months, while at 6 months when the moisture content reached above 4 per cent, activity is stated to decline by 30 to 40 per cent. At 8°C. no loss of potency occurs even though the moisture increased to about 3.3 per cent. It would seem, therefore, that uptake of moisture at low temperatures is not accompanied by loss of activity as rapidly as at high temperatures.

Penicillin solution.—Solutions of commercial penicillin which are available in these days (purer stuff than used to be obtained before) are more stable. The claim of the Glaxo Laboratories regarding the stability of their preparation is apparently based on this. At refrigerator temperature (2°C.), the loss of activity is not seen even after 60 days' storage. Even at a temperature of 36.7°C. (98°F.), penicillin solutions have been found to retain full potency up to 4 days. Therefore it appears that except in hot weather in the plains, it is unnecessary to keep penicillin solution under refrigeration. Ordinarily solutions of penicillin should only be made in quantities which can be used up within 24 hours.

Keeping of penicillin vials in a vacuum flask or in ice-box in actual contact with the ice is not considered a satisfactory method of storage. In many instances, the ice melts and the vials topple over with the result that the cap and the seal comes directly in contact with iced water. This naturally tends to help absorption of moisture, at least in cases where the seal is not absolutely crack-proof. It is definitely better to keep the penicillin bottles in refrigerator, or failing which, in specially designed ice-box where there is no chance of the vial coming in contact with the ice.

UNDIAGNOSED FEVER

Sm,—A coolie woman, aged about 30 years, gave birth to a male child in the early morning of 2nd March, 1947, without any trouble. She had slight temperature since two days before delivery. In the previous evening she had a variable rise of temperature which was not recorded. During confinement it is stated that there was no obvious temperature, but on the day of delivery at about 12 o'clock she got high temperature with shivering and rapidly got unconscious with convulsions.

I attended the case about 3-30. I found her completely unconscious. During my visit she had a convulsion. The temperature was 105°F. Pulse was rapid, voluminous and of high tension. Spleen was felt just below the costal margin and was soft in consistency. Liver was not palpable. Head was not retracted; Kernig's sign negative. Lungs were clear. The temperature persisted throughout the night. Next morning I found the case deteriorating, temperature being the same. The patient finally collapsed and expired at about 2 o'clock.

I gave one injection of quinine gr. x intramuscularly on the 2nd March. The party refused to have any more injections. Two tablets of M&B 693 were administered dissolved in water, but as there was locked jaw throughout, the tablets could not be swallowed. One blood smear was taken on the 3rd March after administration of quinine on the previous day. I shall be obliged if you kindly arrange to get the blood smear examined and let me know the diagnosis.

Yours, etc.,

T. S. BHADURY, L.M.F.

RYDAK TEA ESTATE,
E. DOOARS.

[The blood film shows definite evidence of leucocytosis (about 12,000 to 14,000 per c.mm.) with relative polymorphonuclear preponderance. The differential leucocyte count shows polymorphs 78 per cent, lymphocytes 19 per cent and eosinophils 3 per cent. No malaria parasites have been found, and in view of the absence of parasites, it seems unlikely that it was a case of cerebral malaria. Though the blood was taken after intramuscular administration of a 10-grain dose of quinine in such a fatal case, one is most unlikely to miss the parasites as the film was taken at the height of symptoms. The presence of leucocytosis, though moderate, seems to point towards some sort of an inflammatory condition but it is not really possible to give a definite opinion at this stage.—S. S.]

PROPHYLAXIS WITH TETANUS TOXOID

Sm,—I have the honour to request you to be kind enough to inform me the latest authoritative views about mass prophylactic tetanus inoculation by tetanus toxoid (formalinized toxoid) injection 1 c.c. at the interval of six weeks and six months or one year.

As you know some say three such injections give immunity for life and some say two such injections give protection for two years.

Yours, etc.,

B. PURKAYASTHA.

MURKONG SELEK, P. O.
NORTH EAST FRONTIER,
ASSAM;
14th April, 1947.

[The most notable advance in the prevention of tetanus, the once dreaded disease of the army, was the

introduction in 1938 of the use of tetanus toxoid which, like diphtheria toxoid, is an example of active immunization in advance of exposure. The value of this method of protection is definitely established. Two injections of 1.0 ml. of tetanus toxoid are given with an interval of 6 weeks between the injections followed in a year by a reinforcing or 'boosting' dose of 1.0 ml. repeated at yearly intervals. As a further safeguard against the development of the disease tetanus antitoxin is administered to all considered infected with tetanus bacilli. The minimum dosage of antitoxin is 3,000 international units. This dosage should be increased 2 or 3 times when there is a likelihood of extensive infection.

Certain authorities (American and Canadian) use 3 initial doses of tetanus toxoid instead of 2 given above and instead of the passive protection in case of infections another dose of 1.0 ml. of tetanus toxoid is given as a 'boosting' dose.—C. L. P.]

Service Notes

APPOINTMENTS AND TRANSFERS

LIEUTENANT-COLONEL M. A. JAFARY, Inspector-General of Prisons, United Provinces, is appointed Deputy Director-General, Indian Medical Service, with effect from the 21st February, 1947.

Lieutenant-Colonel D. Kelly, whose services are replaced at the disposal of the Government of C.P. and Berar by the Government of the United Provinces, is posted as Civil Surgeon, Chhindwara, with effect from 28th April, 1947.

Major J. P. Zachariah is appointed Medical Adviser (Pensions), (D. A. D. M. S.), Defence Department (Pensions Branch), 6th November, 1946.

On return from leave, Major T. Sommerville, an officer of the Medical Research Department, was placed on Foreign Service under the Indian Research Fund Association for the period from the 17th December, 1946, to the 31st December, 1946.

Major A. A. Khan, ex-I.M.S. (E.C.), is appointed Deputy Assistant Director-General, Indian Medical Service (Re-settlement), with effect from the 1st March, 1947.

The undermentioned officer of the I.M.S. (E.C.) reverts from the I.A.M.C. and is seconded for service in the Royal Indian Air Force :—

Captain Alland-Din. Dated 27th January, 1947.

LEAVE

Lieutenant-Colonel W. J. Webster, M.C., Assistant Director, Central Research Institute, Kasauli, is granted war concession leave on average pay in India from the 1st January to the 10th February, 1947, and leave ex-India on average pay from the 11th February to the 30th April, 1949, preparatory to retirement.

PROMOTIONS

The undermentioned officer is granted the local rank of Lieutenant-Colonel without effect on pay and pension whilst employed as Surgeon to H.E. the Viceroy :—

Major A. C. Taylor, O.B.E. Dated 20th March, 1947.

Captain to be Major

T. Denness. Dated 28th February, 1946.

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captains to be Majors

B. S. Nagra. Dated 5th June, 1946.

S. I. Sankaran. Dated 6th June, 1946.

W. L. Parnaik. Dated 11th June, 1946.
Sudhir Kumar Das. Dated 30th June, 1946.
R. Anand. Dated 29th August, 1946.
D. S. Piper. Dated 4th October, 1946.

5th October, 1946

S. Virmani. Birbal Sahni.
C. Sen Gupta. Dated 6th October, 1946.
J. W. Lusk. Dated 7th October, 1946.

5th November, 1946

H. K. Das. S. K. Bhattacharjee.
K. M. Kudva. Dated 6th November, 1946.
M. S. Haque. Dated 20th November, 1946.

RELINQUISHMENTS

The undermentioned officer is permitted to relinquish his emergency commission and is granted the honorary rank of Lieutenant-Colonel :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Lieutenant-Colonel W. B. Roantree. Dated 29th December, 1945.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Lieutenant-Colonel :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Ty. Lieutenant-Colonel Sumkar Mitra. Dated 27th January, 1947.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Major. His services are replaced at the disposal of the Government of the Punjab with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Major J. S. P. Conlts. Dated 3rd November, 1945.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Major :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Ty. Major T. Bhadrury. Dated 28th August, 1946.
Major Navroji Manekji Kalapesi. Dated 11th October, 1946.

Major Yugal Kishore Champaram Pandit. Dated 3rd November, 1946.

Ty. Major Sulochan Ghosh. Dated 30th November, 1946.

Major Khushdil Khan Jaswal. Dated 3rd December, 1946.

Ty. Major V. R. M. Sadasivan. Dated 7th December, 1946.

Ty. Major Nazir-ud-Din Fathelali Shaikh. Dated 9th December, 1946.

Major D. K. Bose. Dated 17th December, 1946.

Major Mohd. Khalid Chandhary. Dated 17th December, 1946.

Ty. Major K. Jha. Dated 19th December, 1946.

Ty. Major B. L. Chuckerbutty. Dated 28th December, 1946.

Ty. Major Sunil Kumar Sen. Dated 2nd January, 1947.

Captain V. Krishnamachari. Dated 12th January, 1947.

Ty. Major Man Mohan Nath. Dated 20th January, 1947.

Ty. Major P. K. Kar. Dated 29th January, 1947.

Major Surath Kumar Bhattacharjee. Dated 14th February, 1947.

Major Hazura Singh. Dated 15th February, 1947.
Major Biraj Mohan Sinha. Dated 20th February, 1947.

Major B. S. Nagra. Dated 21st February, 1947.
Ty. Major Aduthorai Perumalkoil Krishnier Ramamurti. Dated 26th February, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain Aylmer Joseph Nicholas. Dated 24th May, 1946.

Captain Alfred David Paul. Dated 21st August, 1946.

Captain H. A. N. Rao. Dated 27th October, 1946.

Captain M. I. D. Sharma. Dated 1st November, 1946.

Captain R. C. Biswas. Dated 6th November, 1946.

Captain K. B. Nair. Dated 22nd November, 1946.

Captain C. J. Aiyandar. Dated 26th November, 1946.

Captain G. V. C. Iyer. Dated 17th December, 1946.

Captain S. K. Dey. Dated 26th December, 1946.

Captain Tejindar Singh Khurana. Dated 2nd January, 1947.

Captain S. M. Bhattacharjee. Dated 13th January, 1947.

Captain Rama Shankar Saksena. Dated 20th January, 1947.

Captain Vithal Sheshgir Joshi. Dated 31st January, 1947.

Captain V. Raghavachar. Dated 2nd February, 1947.

Captain P. G. Saha. Dated 17th February, 1947.

Captain B. Ahmad. Dated 19th February, 1947.

Captain S. C. Srimani. Dated 25th February, 1947.

Captain K. L. Atri. Dated 1st April, 1947.

(WITHIN INDIAN LIMITS)

Captain B. Gupta. Dated 23rd February, 1947.

(WOMEN'S BRANCH)

Captain (Miss) M. K. Verghese. Dated 17th February, 1947.

Captain (Miss) D. E. Thomas. Dated 1st March, 1947.

Captain (Mrs.) M. S. Naidu. Dated 4th March, 1947.

The undermentioned officers are permitted to relinquish their commissions on release from army service and are granted the honorary rank of Captain :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commissions)

Captain K. T. P. Nair. Dated 2nd August, 1946.

Captain J. K. Sen. Dated 27th October, 1946.

Captain S. Mukherjee. Dated 21st November, 1946.

Captain A. K. Nambiar. Dated 1st December, 1946.

Captain K. V. Sharma. Dated 13th December, 1946.

Captain K. S. Seth. Dated 16th December, 1946.

Captain R. S. P. Sinha. Dated 16th December, 1946.

Captain M. A. G. Bhutty. Dated 25th December, 1946.

Captain M. Ahmadi. Dated 11th January, 1947.

Captain P. F. Verghese. Dated 12th January, 1947.

Captain M. J. Verghese. Dated 20th January, 1947.

(WITHIN INDIAN LIMITS)

Captain L. A. F. J. I. Furtado. Dated 23rd January, 1947.

The undermentioned officer is permitted to relinquish his commission on reversion to the Indian State Forces. His services have been replaced at the disposal of the Government of Kashmir State :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain H. R. Gandotra. Dated 23rd March, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is

granted the honorary rank of Captain. His services are replaced at the disposal of the Government of Bombay with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain S. G. Deostnan. Dated 1st March, 1946.

The undermentioned officer is permitted to relinquish his commission on release from army service and is granted the honorary rank of Captain. His services are placed at the disposal of the Government of Mysore with effect from the date specified :—

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain K. S. Shadakharappa. Dated 2nd August, 1946.

The undermentioned officer is permitted to relinquish her commission on release from army service and is granted the honorary rank of Captain. Her services are placed at the disposal of the Government of Burma from the date specified below :—

(WOMEN'S BRANCH)

INDIAN LAND FORCES—INDIAN MEDICAL SERVICE
SECONDED TO THE INDIAN ARMY MEDICAL CORPS

(Emergency Commission)

Captain (Miss) J. M. Gaudsin. Dated 16th August, 1946.

Publishers' Notice

SCIENTIFIC Articles and Notes of interest to the profession in India are solicited. Contributors of Original Articles are entitled to receive 25 reprints *gratis*; additional reprints can be obtained on payment. No reprints will be supplied unless contributors ask for them at the time of submitting their manuscripts.

The preparation of reprints entails rearranging the type, so that there is often a delay of a month or more, after the publication of the *Gazette*, before the reprints are ready. If reprints are not received within two months of publication of the *Gazette*, contributors should write to the Publishers.

Papers and articles forwarded for publication are understood to be offered to *The Indian Medical Gazette* alone, and any breach of this rule will be followed by non-publication. When any such article appears in *The Indian Medical Gazette*, the copyright automatically becomes the joint property of the author or authors and of the publishers.

Communications on Editorial Matters, Articles, Letters and Books for Review should be addressed to THE EDITOR, *The Indian Medical Gazette*, c/o The Calcutta School of Tropical Medicine, Central Avenue, Calcutta.

Communications for the Publishers relating to Subscriptions and Advertisements should be addressed to THE PUBLISHERS, *The Indian Medical Gazette*, P. O. Box No. 54, Calcutta.

Annual Subscription to '*The Indian Medical Gazette*', Rs. 16 including postage, in India. Rs. 19-8 including postage, abroad. Single copies Re. 1-8 each. Back numbers (if available) for the previous year Rs. 2-8 each, and all other back numbers Rs. 5 each.

The Editors of *The Indian Medical Gazette* cannot advise correspondents with regard to prescriptions, diagnosis, etc., nor can they recommend individual practitioners by name, as any such action would constitute a breach of professional etiquette.

THE VALUE OF TRANSFUSION OF BLOOD IN THE TREATMENT OF ANÆMIAS *

By C. R. DAS GUPTA, M.B., D.T.M. (Cal.)
Hæmatology Research Department, School of Tropical Medicine, Calcutta

TRANSFUSION of blood has long been recognized as an effective therapeutic agent in the treatment of anæmias. Judicious transfusion of blood, along with other measures, has been found to give very satisfactory results even in cases of severe anæmias. The present-day tendency has, however, been to rely entirely or unduly on the transfusion of blood alone in the treatment of any case of severe anæmia without any reference to the type of anæmia and the probable ætiology of the condition. The purpose of this paper is to assess the value of transfusion of blood in the different types of anæmia which were treated in the Carmichael Hospital for Tropical Diseases during the past few years.

Almost all the patients were Indians and were either Hindus or Muslims. On admission each patient was subjected to a thorough investigation, clinical and laboratory. The investigations included a complete cytological examination of the blood as to the type and degree of anæmia, as also examination of the blood for malaria, kala-azar, and syphilis; examination of the bone marrow by sternal biopsy; fractional gastric analysis; examination of the stool for any helminthic ova and protozoa; and examination of the urine for any abnormality. Special examinations, e.g. skiagrams of the chest or skull, were done wherever indicated.

On the basis of the investigations and for the purpose of this paper the cases of anæmias are classified under the following groups:—

A. *Deficiency dyshæmopoietic anæmias.*—

- (i) Nutritional macrocytic anæmia.
- (ii) Nutritional hypochromic anæmia.
- (iii) Dimorphic anæmia.

B. *Anæmia associated with some infection or infestation.*—

- (i) Kala-azar.
- (ii) Malaria.
- (iii) Hookworm.

C. *Anæmia associated with blackwater fever.*D. *Anæmia associated with aplasia of the marrow.*E. *Anæmia associated with other disorders of the blood.*—

- (i) Leukæmias.
- (ii) Essential thrombocytopenia.

F. *Anæmias in the childhood.*—

- (i) von Jaksch's anæmia.
- (ii) Cooley's anæmia.

The effect of transfusion of blood in the different groups

The procedure adopted in the treatment of anæmias and of any associated condition, if present, varied in the different groups and will be briefly described under their respective heads. The response to treatment with, or without, transfusion will be discussed in some details in cases of deficiency anæmias and short comments will be given in other cases.

A. *Deficiency dyshæmopoietic anæmias*

The first step in the treatment of the deficiency anæmias was the administration of the correct hæmatinics in adequate dosage as soon as the investigations were completed. Transfusion of blood was given at the outset along with the proper hæmatinics only to a very few cases of severe anæmia with debilitated conditions. Transfusion of blood was more generally given at the later stages to cases not responding well to hæmatinics. The response to treatment in 284 cases of deficiency anæmias with or without transfusion is shown in table I. A few representative charts along with short notes to illustrate the effect of transfusion of blood under different conditions are given.

Illustrative cases(a) *Cases of profound anæmia improving with hæmatinics alone without any blood transfusion.*—

Cases of nutritional macrocytic anæmia with red cell count of one million or below, but having cellular and megaloblastic marrow, have been found to improve remarkably well with hæmatinics alone. The improvement is about the same with crude liver extracts given parenterally (Das Gupta, 1943) with proteolysed liver given orally (Das Gupta, Ganguli and Chatterjea, 1946), or with synthetic folic acid (Lederle) also given orally (Das Gupta and Chatterjea, 1946).

Case 1.—Mrs. M., 25, was admitted with a red cell count of 0,700,000 per c.mm. Sternal puncture showed active megaloblastic marrow. The patient showed remarkable improvement with crude liver extracts given parenterally. With 12 injections given in course of 15 days, the red cell count went up to 3,410,000 per c.mm. in exactly 30 days (graph 1).

Case 2.—H. S. P., male, 21 years of age, was admitted with a red cell count of 0,970,000 per c.mm. Investigations showed that he was a case of macrocytic anæmia with cellular megaloblastic marrow. The patient improved rapidly with proteolysed liver given orally. The

* Read in the thirty-fourth session of the Indian Science Congress.

TABLE I
(i) *Nutritional macrocytic anæmia*

Level of red cell count	Number of cases	With transfusion number	Without transfusion number	RESULTS			
				With transfusion		Without transfusion	
				Improved	Died	Improved	Died
0.500,000 and below	5	1	4	Nil	1 (1-x-x)	3	1
Over 0.500,000 and up to 1,000,000.	52	14	38	10 (2-5-3)	4 (1-2-1)	36	2
Over 1,000,000 and up to 1,500,000.	52	9	43	6 (3-1-2)	3 (2-1-x)	39	4
Over 1,500,000 and up to 2,000,000.	28	3	25	3 (3-x-x)	Nil	25	Nil
Over 2,000,000 ..	33	Nil	33	32	1
All cases ..	170	27	143	19	8	135	8

(ii) *Nutritional hypochromic anæmia*

Level of hæmoglobin	Number of cases	With transfusion number	Without transfusion number	RESULTS			
				With transfusion		Without transfusion	
				Improved	Died	Improved	Died
3 gm. and below ..	6	1	5	1 (1-x-x)	Nil	4	1
Over 3 gm. and up to 5 gm.	20	2	18	2 (2-x-x) Not	Nil	18	Nil
Over 5 gm. and up to 7 gm.	34	1	33	1 (1-x-x)	Nil	32	Not improved 1
Over 7 gm. ..	14	Nil	14	..	Not improved	14	Not improved
All cases ..	74	4	70	3	1	68	1

(iii) *Dimorphic anæmia*

Level of red cell count	Number of cases	With transfusion number	Without transfusion number	RESULTS		
				With transfusion	Without transfusion	
				Improved	Improved	Not improved
1,000,000 and below	4	1	3	1 (1-x-x)	3	..
Over 1,000,000 and up to 1,500,000.	18	Nil	18	..	17	1
Over 1,500,000 and up to 2,000,000.	12	Nil	12	..	12	..
Over 2,000,000 ..	6	1	5	1 (1-x-x)	5	..
All cases ..	40	2	38	2	37	1

Indication of the figures in bracket under the head 'with transfusion'—

The first figure indicates—the number of cases having 1 transfusion.

The second " " " " " " " " 2 transfusions.

The third " " " " " " " " 3 " or more.

red cell count went up to 3,460,000 per c.mm. in 33 days after two courses of proteolysed liver extract given within 25 days, with an interval of 5 days between the courses. Without any

further treatment the red cell count went up to 4,340,000 per c.mm. in three weeks (graph 2).

Case 3.—J. A., male, 30, was admitted with a red cell count of 0,950,000 per c.mm. Investigations showed that he was a case of macrocytic anæmia with megaloblastic marrow but with low gastric acidity. Administration of synthetic folic acid (Lederle) was followed by rapid improvement of the blood picture, the red cell count going up to 3,700,000 per c.mm. in about 30 days (graph 3).

(b) Cases of profound anæmia improving with hæmatinics and transfusion.—In cases of very severe anæmia associated with marked debility, transfusion of blood is always given whenever suitable blood is available, along with hæmatinics with very good results.

Case 4.—Mrs. K. S. C., 33, was admitted in a very debilitated state with a red cell count of 0,660,000 per c.mm. Investigations showed macrocytic type of anæmia with megaloblastic marrow. On account of the debilitated condition, the patient was given two quick transfusions

of blood within one week of her admission into the hospital along with liver injections. The improvement was quite rapid, the red cell count

going up to 3,380,000 per c.mm. in 30 days (graph 4). It is to be noted that though the patient had had two transfusions along with liver injections, the rate of improvement in this case

was not very much more rapid than in cases 1, 2 and 3, each of whom improved rapidly with hæmatinics alone.

(c) Cases of macrocytic anæmia not improving with liver extracts alone but improving with liver extracts and transfusion of blood.—(i) Some cases of macrocytic anæmia with cellular megaloblastic marrow may not improve with hæmatinics alone but will improve when transfusion of blood is given along with hæmatinics.

Case 5.—S. C., male, 32, was admitted with a red cell count of 1,580,000 per c.mm. The patient did not respond to T.C.F. liver injections, but he showed some improvement when some more liver injections of a different brand, campolon, were given along with a transfusion of blood. The patient showed still further improvement with another course of campolon injection and a second transfusion given along with it—(graph 5). Clinical improvement noted after both the transfusions as also the sub-maximal improvement after the first course of campolon would support the contention that the

change of brand of liver extract was not the only factor in effecting improvement in this case.

(ii) Cases of macrocytic anæmia with hypocellular marrow generally do not respond to

hæmatinics alone but may respond to hæmatinics in big dosage and repeated transfusions.

Case 6.—S. C. G., male, 40, a case of macrocytic anæmia with hypoplastic marrow did not respond at first to hæmatinics in the usual dosage although two transfusions were given during the first few days. Continuation of the treatment with big doses of liver injections of the same brand and a few more transfusions given at short intervals produced fair response (graph 6).

(d) Late response to hæmatinics and multiple transfusions in cases of macrocytic anæmias.—Some cases, specially those with big spleen, in spite of hypercellular megaloblastic marrow may not improve with hæmatinics and transfusion in the usual way. Many of these cases would, however, show good improvement with reduction in size of the spleen, if treatment with hæmatinics and transfusion be continued over a long period.

Case 7.—B. N. S. R., male, 16, was reported to be suffering from huge enlargement of the

spleen and anæmia for over five years. Investigations on admission showed that the boy had severe anæmia having a red cell count of 1,120,000 per c.mm. The anæmia was macrocytic in character. The bone marrow was very cellular and megaloblastic in reaction. Fractional gastric analysis showed absolute achlorhydria. The patient did not respond at all to treatment with potent liver injections and transfusions for the first four months. Continuation of treatment with liver extracts and transfusions produced very satisfactory hæmatological and clinical improvement including reduction of the size of the spleen. It is to be noted that the patient responded to the same liver extract in the later stage which had failed to produce any improvement in the earlier stages (graph 7).

(e) Cases not improving with multiple transfusions in the absence of any hæmatinics or in combination with incorrect hæmatinics but responding to the correct hæmatinics without any further transfusion.—Not infrequently transfusion of blood is given without proper investigations. In some cases only repeated transfusions are given while in others incorrect hæmatinics is given along with the transfusions with discouraging results in both groups of cases. Treatment with proper hæmatinics alone would help to improve the blood picture in these cases without any further transfusions.

Case 8.—For over six months, the patient, Mrs. P. N., was treated with liver extracts of different brands along with repeated transfusions, having 14 transfusions in about six months, without any appreciable improvement. On admission examination of the blood and of the bone marrow revealed that the anæmia was dimorphic in type. Administration of iron alone was followed by rapid improvement of the blood picture, later administration of another course of liver extract improved the blood picture still further. The combined treatment helped to bring the blood values to about the normal level in a little over one month (graph 8).

Case 9.—On account of severe anæmia, N. S., male, 32, was given two transfusions of blood in about two weeks and a few injections

of liver extract of doubtful potency in inadequate dosage without any appreciable improvement. On admission into our hospital investigations showed that the patient was suffering from

macrocytic anæmia and had cellular megaloblastic marrow. Administration of potent liver extract in adequate dosage improved the blood picture in a short time (graph 9).

(f) *Refractory cases.*—Occasionally cases of macrocytic anæmia are seen which in spite of active megaloblastic marrow would not improve on liver extracts and multiple transfusions.

Case 10.—J. H., male, 22, was a case of macrocytic anæmia with cellular megaloblastic marrow and normal gastric acidity. The patient showed only slight improvement in spite of continued treatment with potent liver extracts and transfusions for about five months. Unfortunately, marmite could not be tried on this patient on account of non-availability of marmite. The patient left hospital and his subsequent history was not known (graph 10).

This case of macrocytic anæmia with megaloblastic marrow and normal gastric acidity closely resembles achrestic anæmia of Israëls and Wilkinson (1940), on account of its failure to respond to potent liver extracts.

B. Anæmia associated with some infection or infestation

(i) *Anæmia associated with kala-azar.*—Analysis of cases of kala-azar admitted under Dr. P. C. Sen Gupta, Kala-azar Research Worker, for the last two years, would show

that the anæmia associated with kala-azar is generally of mild to moderate degree (table II). Treatment of kala-azar with suitable drugs in adequate dosage is sufficient not only to eradicate the infection but to correct any mild to moderate degree of associated anæmia. In the few cases of severe anæmias administration of suitable hæmatinics along with the specific treatment or after a course of specific treatment may be required to bring the blood picture to the normal level. Transfusion of blood may be given with advantage to some of these cases not improving well with specific treatment and hæmatinics. But it must be emphasized here that non-improvement of the blood picture is, generally, an indication of non-eradication of the infection and would call for more vigorous treatment of kala-azar. Transfusion of blood has also been found to be very helpful in the treatment of cases complicated with cancerum oris, etc. But in cases of kala-azar, even with profound anæmia, transfusion of blood alone is absolutely of no value in improving the condition of the patient, as will be seen from the following case:—

Case 11.—S., male, 28, was treated with repeated transfusions and indifferent hæmatinics for over two months on account of severe anæmia with very little improvement. On admission into our hospital, examination of the bone marrow by sternal biopsy showed numerous Leishman-Donovan bodies. Subsequent treatment for kala-azar together with hæmatinics and transfusion of blood and plasma (given on account of hypoproteinæmia) helped to cure the patient (graph 11).

The patient was discharged shortly after the 1946 August disturbances without any further blood examination. He was seen after about two months when he appeared to be absolutely normal.

TABLE II

Level of red cell count	Number of cases	With transfusion number	Without transfusion number	RESULTS			
				With transfusion		Without transfusion	
				Improved	Died	Improved	Died
1,000,000 and below	5	4*	1	3	1	Nil	1
Over 1,000,000 and up to 1,500,000.	7	2†	5	2	Nil	5	Nil
Over 1,500,000 and up to 2,000,000.	8	1	7	1	Nil	7	Nil
Over 2,000,000 ..	60	Nil	60	60	Nil
All cases ..	80	7	73	6	1	72	1

* 3 cases with cancerum oris.

† 1 case with cancerum oris.

(ii) *Anæmia associated with malaria.*—Over 200 cases of malaria were treated by the Professor of Tropical Medicine (Dr. J. Lowe and Dr. R. N. Chaudhuri) during the last three years. It was noted that patients suffering from acute malaria, with parasite in the peripheral blood, usually do not show any marked degree of anæmia. Eradication of the infection with suitable antimalarial drug is generally sufficient to correct any associated anæmia as well. Any patient with severe degree of anæmia should, however, always be treated with suitable hæmatinic, according to the type of anæmia, along with adequate dose of any potent antimalarial drug. Ordinarily, transfusion of blood is not indicated in the treatment of anæmia associated with malaria, but transfusion of blood must always be given if examination of the bone marrow would show hypocellular marrow.

(iii) *Hookworm anæmia.*—Treatment with adequate dose of ferrous iron at the outset, irrespective of the degree of anæmia, deworming the patient with proper anthelmintic when the blood picture has been sufficiently raised by initial iron treatment, further course of iron, if required, to bring the blood values to the normal level, are required for properly diagnosed

cases of hookworm anæmia (Napier, Das Gupta and Majumdar, 1941). Even in the cases with very low blood counts, transfusion of blood would be superfluous as will be seen from an analysis of the cases given in table III.

TABLE III

Level of hæmoglobin	Number of cases	With transfusion number	Without transfusion number	Results improved number

Over 5 gm. and below 7 gm.	11	Nil	11	11
Over 7 gm.	9	Nil	9	9
All cases ..	57	Nil	57	57

C. *Anæmia associated with blackwater fever*

In cases of blackwater fever the blood values fall to very low levels within a very short time. In the majority of cases, with the cessation of the hæmolytic process, the blood values improve as rapidly as they fell, without the help of any hæmatinic or transfusion. Transfusion of blood must however be always given in cases where hæmoglobinuria persists for some days.

Case 12.—C. C., male, 32, was admitted with blackwater fever and severe anæmia. Hæmoglobinuria subsided within a day of his admission into the hospital and with it there was rapid improvement in the clinical and hæmatological conditions of the patient. Without any hæmatinic or transfusion, the blood values, from very low levels, reached almost the normal levels in less than four weeks' time (graph 12).

D. *Anæmia associated with aplasia of the marrow*

In cases of aplastic anæmias, diagnosed by sternal puncture, no treatment, not even

repeated transfusions along with all the known hæmatinics given together, would be able to improve the blood picture, and death generally follows in a few months. Exception is provided by the cases where aplasia of the marrow is temporarily produced by some severe infection, which is amenable to treatment as in cases of kala-azar associated with agranulocytosis. Aplastic nature of the marrow can only be detected by examination of the bone marrow and can seldom be inferred from

examination of the blood alone, however complete it may be. History of repeated attacks of malaria with insufficient treatment is given by some of the cases with aplastic bone marrow but malaria parasite has never been found either in the blood or in the bone marrow of any of these cases. In the absence of any post-mortem examination it is not possible to say if repeated attacks of malaria could lead to aplasia of the marrow in certain individuals.

Case 13.—Dr. S., male, 51, engaged in x-ray works, was admitted for treatment of anæmia.

Examination of the bone marrow showed aplasia of the marrow. Repeated transfusion at short intervals, once every week along with hæmatinics, failed to improve the blood picture and the patient died within three months (graph 13).

E. Anæmia associated with other disorders of the blood

(i) *Leukæmias*.—Transfusion of blood is of great palliative value in the treatment of bleeding in leukæmias but transfusion should not be used as a curative measure (Forkner, 1938). Castle et al. (1935) are of opinion that frequent transfusions provide only temporary benefit and is not associated with any change in the leucocytes.

In acute leukæmias, transfusion of blood may prolong life for a short time but repeated transfusions of blood have not been found to affect the course of the disease.

In chronic myeloid leukæmias, transfusions of blood may act as a valuable help when given in conjunction with judicious dose of x-ray. Transfusion of blood alone, however, is of little value in the treatment of these cases.

(ii) *Essential thrombocytopenia*.—Transfusion of blood is invaluable in combating any severe hæmorrhage, which is not infrequent in these cases. Jones and Tocantins (1933) claim to have cured a large number of cases with repeated transfusions given at intervals of 4 to 5 days. Transfusion of blood is also of immense value in the pre-operative stage or after operation (splenectomy), specially in the cases with any associated anæmia.

F. Anæmia of childhood

(i) *Type von Jaksch*.

(ii) *Type Cooley*.

Anæmia in both these types, specially in Cooley's type, is generally refractory to treatment with hæmatinics and transfusions. Transfusions of blood may, however, help to raise the blood counts temporarily, and repeated transfusions of blood along with hæmatinics may be helpful in some cases with severe anæmia.

Case 14.—B., female child, age 6 years, a chronic sufferer from anæmia from infancy, was admitted with a red cell count of 1,320,000 per c.mm. For about ten months the blood levels were kept moderately high with repeated transfusions and hæmatinics. With the cessation of treatment after discharge from the hospital both the hæmoglobin and the red cell count fell to very low levels within a short time and the patient died (graph 14).

Summary and conclusion

It has been shown that the treatment of anæmia varies from case to case and is dependent on the type and degree of anæmia as also on the underlying cause. The majority of the cases of deficiency anæmias were treated with hæmatinics alone without any transfusion. The percentage of improvement in the cases treated with hæmatinics alone, including the cases with very severe anæmia, was very high and was even higher than in the cases who had had transfusion as well. This was probably due to the fact that moribund cases and cases not responding well to hæmatinics were generally selected for transfusion. Comparing the rate of improvement in the cases of nutritional macrocytic anæmia showing rapid improvement with hæmatinics alone or in combination with transfusion, it will be seen that the rate of improvement was apparently of the same order in both the groups.

In the group of cases with infection or infestation, eradication of the infection with specific treatment was all that was necessary in most cases of malaria and kala-azar for the improvement of any associated anæmia, while combined treatment with iron and anthelmintic was essential for the treatment of hookworm anæmia of any degree. In the absence of any associated complications, *e.g.* cancrum oris in kala-azar, and in the absence of any severe anæmia, transfusion of blood is not generally indicated in the treatment of any associated anæmia in this group of cases.

Transfusion of blood, however, is a valuable adjunct in the treatment of any severe case of anæmia with hypocellular marrow and in the treatment of refractory cases, in conjunction with appropriate hæmatinics, and specific treatment for any associated infection, if there be any. It has been seen that if refractory cases of macrocytic anæmia with cellular megaloblastic marrow could be kept alive for a few months with hæmatinics and transfusions, some of them at least would respond later, and respond well, to the same hæmatinics which failed to produce any improvement in the earlier stages. Transfusion of blood has also been found to be a good supporting treatment in cases of essential thrombocytopenia and chronic myeloid leukæmia in combination with other therapeutic measures. But it is only of some temporary value in cases of Cooley's and von Jaksch's anæmias and of doubtful value in cases of aplastic anæmia.

Transfusion of blood alone will seldom, if ever, effect a cure in any case of anæmia enumerated above, whereas administration of the correct hæmatinic in adequate dosage and treatment of any associated condition, if there be any, will improve the blood picture of a very large number of these cases, including the cases with severe anæmia. Therefore, complete

cytological examination of the blood to determine the type and degree of anæmia, examination of the sternal bone marrow to find out the cellularity and the reaction of the marrow, and a thorough investigation to find out any associated condition, are essential pre-requisites in determining the mode of treatment of any case of anæmia, mild, moderate, or severe.

Acknowledgment

My thanks are due to Dr. J. B. Chatterjea, Assistant Research Worker, Hamatological Unit, I.R.F.A., for assistance in preparing the paper.

THE EFFECT OF PROCESSING AND SOURING MILK BY THE INDI-GENOUS METHOD

By K. S. RANGAPPA, M.Sc. (Bom.)

(From the Department of Biochemistry, Indian Institute of Science, Bangalore)

HEAT treatment of milk is a well-known and widely-adopted device for improving the storage life of milk either as such or before souring it. While in the West scalding or the more recent high-temperature short-time method of pasteurization is practised, boiling of milk is the time-honoured custom in India. Srinivasan and Banerjee (private communication) have shown that boiling for 10 minutes is more efficient than pasteurization in bringing down the bacterial count from over 100,000 to less than 100 per c.c. Anantakrishnan and co-workers (1943) have recorded the chemical changes occurring on boiling milk, and reported as a loss the contents of the skin formed on the surface of milk after boiling and cooling. But as the practice stands in the Indian household the skin is invariably utilized for making curd, butter or confectionery. In this paper the chemical changes on boiling milk for 10 minutes without allowing the skin to be formed, and the rise in the bacterial count of the processed milk with keeping have been recorded. Further, the processed milk has been soured with seed curd, and the multiplication of bacteria

during the process, and the count of the resulting butter and buttermilk have been studied.

Experimental

In order to study the growth of bacteria in processed milk on keeping 2 litres of freshly drawn buffalo milk were collected in a clean, steamed aluminium can in the dairy farm, brought to the laboratory and at once plated in standard nutrient agar. The milk was then set to boil in a tinned-brass vessel of 4 litre capacity over a Primus stove, and continuously stirred with a wooden ladle to prevent the formation of skin and residue as well as boiling over of the milk. The time lapse between milking and setting the milk to the boil was 1 to 1.5 hours. The milk was brought to boil, kept boiling (95° to $96^{\circ}\text{C}.$) for 10 minutes and then cooled to room temperature (23° to $25^{\circ}\text{C}.$), keeping up the stirring all the time, the total time thus taken for processing being 20 to 25 minutes. While repeating the experiment it was observed that the count of the boiled milk which was cooled in the open vessel as well as the rate of multiplication of bacteria on keeping the milk were considerably higher than those obtained when the boiled milk was at once poured into a conical flask, plugged with cotton-wool and then cooled. The experiment was therefore repeated both ways; and the processed milk in the conical flask was stored in a cupboard at room temperature (19° to $31^{\circ}\text{C}.$). The standard agar count was estimated at intervals of a few hours. The rises in the count on keeping are given in table I. In the same table the results of a similar experiment on pasteurized milk (Rep. Marketing of Milk in India and Burma, 1943) are entered for comparison.

In the above experiment the change in composition due to processing were also estimated by measuring the density (lactometer), fat (Gerber process), total solids, lactose and ash of milk (Woodman, 1941) before and after processing. The differences are recorded in table II.

The rate of multiplication of bacteria on souring was studied by seeding 2.5 per cent by volume of a homogeneously set curd of 1.0 to 1.1 per cent lactic acidity into a litre of buffalo milk processed as before. The flask was kept in an electric incubator at $40^{\circ} \pm 1^{\circ}\text{C}.$, and

	Curd was churned into butter		
	Butter	52,000	
	Buttermilk	Teeming at 1 : 100,000,000 dilution	

Discussion

It is clear from the figures in table I that bacterial destruction in milk is not only much more efficient with boiling for 10 minutes than with pasteurization but the rate of multiplication of organisms on keeping is considerably less in the former case. The bacterial quality of milk and, therefore, its keeping quality, is further improved by transferring the boiled milk at once into a closed vessel and then cooling it. The ease of operation and the needlessness of any elaborate or specialized equipment makes this method eminently suited for conditions obtaining in this country, where small-scale production in rural areas is the rule.

This type of processing, it will be observed from table II, reduces the volume by about 20 per cent, and raises the total solids by about 3.3 per cent, fat by 1.2 per cent and lactose by 1.1 per cent. The allowance is, however, made for the reduction in volume, a loss of 0.28 per cent of total solids, 0.1 per cent fat and 0.14 per cent lactose is observed. Kieferle and Gloetzel (1930) have similarly noted a slight loss in lactose—and proteins on boiling milk for 30 minutes. Gould (1945) has recorded a destruction of 25 to 30 per cent of lactose on still more rigorous (2.5 hours at 116°C . or 8 hours at 100°C .) processing.

In table III, apart from the quick rise in bacterial count with the progress in souring, the most significant fact is the uneven distribution of the bacterial population of curd between butter and buttermilk on churning: almost all the organisms pass into buttermilk leaving a very small fraction in butter, a fact also observed by Grimes (1923) and Hammer and Nelson (1940) in the creamery process. The low count butter produced by the indigenous method as described above compares very favourably with that produced under the best of conditions by the creamery process.

Summary

Milk boiled for 10 minutes and preserved in a closed vessel not only brings down the bacterial count more efficiently than does pasteurization, but the rate of growth of organisms on keeping it is considerably less than in pasteurized milk. The simplicity and efficiency of the method perfectly suits the small-scale village producer in India.

The rise in the plate count of boiled milk on souring has also been studied. On churning the curd almost all the organisms pass into the buttermilk leaving a very small number in butter.

My thanks are due to Mr. B. N. Banerjee and Professor V. Subrahmanyam for their kind interest in these investigations.

BRENNER TUMOUR OF THE OVARY: REPORT OF TWO CASES, ONE IN THE WALL OF A SEROUS CYSTADENOMA

By Y. M. BHENDE, M.D.

(Department of Pathology and Bacteriology, Seth Gordhandas Sunderdas Medical College, Bombay)

BRENNER (1907) was the first to separate as a distinct entity the tumour which goes by his name. He called it 'oopheroma folliculare' but failed to recognize its true nature. In a diligent search of the literature Fox (1942) discovered that nine others, before Brenner, had been similarly misled. In retrospect, almost by a general consensus of opinion, Orthmann (1899) is given the credit for having described the first case of this neoplasia (Gaines, 1936; Novak and Jones, 1939; Geist, 1942). The present status of the Brenner tumour, however we owe to Meyer (1932) who described in detail its pathological characteristics, segregated it from the general mass of granulosa cell tumours and proposed for it a mode of histogenesis which still remains the most accepted one.

Pathologic anatomy

Gross characteristics.—The commoner variety is the solid one. The size may vary from a

microscopic nodule of typical cellular aggregates to a large mass as big as an adult's head. The largest solid tumour recorded so far weighed 15 pounds (Neiman, 1936). It forms a well-circumscribed nodular mass compressing the surrounding ovarian tissue but without a definite fibrous capsule. The consistency is firm. The cut surface is pale, avascular and like that of a dense fibroma; a yellowish tint, if present, is significant. In the larger tumours small discrete cysts with mucoid contents may be visible; the tendency to cystic degeneration or necrosis is, however, not marked (Novak, 1940). The less common type occurs as a solid nodule in the wall of a cyst. The solid nodule forms a small mass, a few cm. in diameter, and has the same appearance as that of an independent solid tumour. The cyst which bears the nodule in its wall may be either a pseudo-mucinous cystadenoma or a serous cystadenoma; the latter type is exceedingly rare. Geist (1942) believed that the cyst was formed by the coalescence of smaller cysts in a tumour originally solid. According to Meyer the cyst may be entirely independent and the Brenner nodule a separate development in its walls (Geist, 1942).

Microscopic characteristics.—Epithelial cell islets enmeshed in a fibrous groundwork form the characteristic histological picture. Both of these elements must be present to justify the diagnosis (Novak, 1940). The epithelial cell nests are composed of larger polyhedral cells with small oval vesicular nuclei. The peripheral rows of these cells may show a palisade arrangement. Danforth (1942) found that these nuclei have a peculiar 'tagged' appearance because of a tiny groove or fold traversing the longitudinal axis of the nucleus. He found the same structure for the nucleus of the epithelial lining of the pseudo-mucinous cystadenoma and further quotes Ivy who described a similar nuclear configuration for the Sertoli cells of the testis. But neither the appearance of the cells nor the nuclear pattern proclaim a highly proliferative activity for the neoplastic cells. There is a tendency for central cystic degeneration in these epithelial cell groups; the mucoid product that results takes the mucicarmine stain. In such a case the innermost lining of the tiny cyst shows nuclei placed away from the lumen—a point of distinction from the granulosa cell tumour. Yet another interesting feature is that the superficial layer in such cystic cavities may be transformed into mucoid columnar epithelium. The epithelial cells of the Brenner tumour contain glycogen but never lipid—another point of distinction from the granulosa cell tumour. The connective tissue component forms dense collagenous stroma surrounding the epithelial islets; no stromal elements can be demonstrated in between the epithelial cells. The stroma may occasionally show hyaline and calcareous degeneration.

Additional interesting features

Dockerty and MacCarty (1939) encountered a case of a Brenner tumour with an old corpus luteum at its lower pole, suggesting, as they remarked, that the 'ovarian function to this extent was not affected'. Plaut (1933) came across a miniature Brenner tumour in the torn wall of a lutein cyst. Rogers (1943) found in the literature records of four cases of Brenner tumour associated with pregnancy and he reported the fifth case. Abraham (1933) recorded one case associated with endometriosis. Fox (1942), among 170 cases of Brenner tumour in the literature, came across thirteen cases (7.6 per cent) in which the growth was bilateral. Johnson and Dockerty (1945) recorded the fourteenth case. Brenner tumour on one side may be associated with a different lesion in the other ovary: lutein cysts, fibromas, granulosa cell tumours and carcinomas have been described (Geist, 1942). A small proportion of pseudo-mucinous cystadenomas of the ovary have their origin in Brenner tumours (Novak, 1940). Meyer (1932) believed that serous cystadenomas of the ovary may have a similar origin. Novak (1940) remarked that a careful study of many supposed simple fibromas of the ovary would show them to be of Brenner variety.

Clinical characteristics

The most frequent age period for the Brenner tumour is after the menopause, beyond the age of fifty. Plaut (1933), Bland and Goldstein (1935), and Novak (1940) found that no genuine case of this neoplasm had been observed in a child. On the other hand, Geist (1942) stated that the Brenner tumour had been reported both in fancy and old age and further quoted Neumann as having cited a bilateral tumour in a child of five. The only symptoms and signs produced are those due to its size and its situation; there are no symptoms or signs that are pathognomonic. The disturbances of menstrual function or atypical uterine bleeding, described in some of the cases (Schiffmann, 1932), are due to the associated lesions (Novak, 1940). Ascites is occasional (Bland and Goldstein, 1935; Novak, 1940; Johnson and Dockerty, 1945), though Geist (1942) discountenanced this occurrence. Even Meig's syndrome has been described (Johnson and Dockerty, 1945) but would appear to be extremely rare. The general trend is to deny any endocrine influence for these neoplasms. Its growth is a very slow one and in spite of a few cases in the older literature suggesting recurrence (Tawildaroff, 1919) or malignant change (Voigt, 1903), apparently accepted by Bland and Goldstein (1935), the neoplasm is essentially a benign one (Novak, 1940; Geist, 1942).

Histogenesis

The histogenesis of the Brenner tumour has not been finally settled. The original conception

of Brenner (1907) that his 'oopheroma folliculare' was derived from the follicle of the ovary or the Pflüger's tubules and was therefore a specialized type of the granulosa cell tumour is no more accepted. Meyer's (*loc. cit.*) explanation that these neoplasms arise from the indifferent cells of the Walthard islets is the most accepted one at the present moment. It is interesting to recall that, in his original description of this neoplasm, Orthmann (1899) suggested this origin (Novak and Jones, 1939). Schiller (1934, 1936), on the basis of his microscopic studies showing a close resemblance between certain glands of the posterior urethra and the epithelial islets of the Brenner tumour and the abnormal persistence of the embryonic relationship between the rete ovarii and the epoophoron tubules in the hilum of the ovary, concluded that the neoplasm arose from the rete. Dockerty and MacCarty (1939) and Dockerty (1941) thought it to be one-sided development of a teratoma. Novak (1940) added yet one more possibility that the areas of epithelial metaplasia found not infrequently on the surface of the ovary in chronic perioophoritis may be the source of origin. Plaut (1933) believed that not all the so-called Walthard's rests were embryonic in nature; they could originate during life from the peritoneal epithelium.

Incidence

This interesting neoplasm would appear to be a rare entity. Meyer (*loc. cit.*) came across four cases in twenty years. Szathmáry (1933) found five cases among his material of 1,114 ovarian neoplasms. Novak (1940) came across 19 instances among more than 48,000 specimens. Within a period of forty years 20 Brenner tumours were encountered in the files of the Mayo Clinic (Johnson and Dockerty, 1945). Of the 500 solid ovarian neoplasms reviewed by Dockerty (*loc. cit.*) 2 per cent were of the Brenner type. Fox (1942) computed that about 170 cases had been reported so far. The *Quarterly Cumulative Index Medicus* recorded seven more cases up to the end of 1945.

From this country Gharpure (1941) reported a single case of a 'papillary fibroma inside the wall of serous cystoma, ? Brenner tumour of the ovary'. Menon and Veliath (1943) encountered a single case in their series of 204 ovarian neoplasms. Within a period of twenty-two years the writers have seen two cases.

Case reports

Case 1 (3371) R.—Solid Brenner tumour.

Clinical history.—A Christian female, aged 45, was admitted to the surgical side for pain in the abdomen. About three months ago she had an acute attack of severe pain in the right lower quadrant of the abdomen. Nausea accompanied the pain but there was neither any vomiting nor any rise of temperature. It was diagnosed as 'acute appendicitis'. It

subsided with rest and internal medication. Since then she was having similar but milder attacks off and on. Nausea, and a distaste for all kinds of food, accompanied the pain. Her menstrual period started at the age of sixteen; she had her last period a fortnight ago. The menses had always been regular, painless, and moderate. She had a single normal delivery; the child died when a year old. The only episode to note in the past history was an attack of frequency stools with passage of blood and mucus about twenty years ago.

Examination showed a well-built and well-nourished woman. Temperature 97.4°; pulse 78; and respiration 26. Abdominal palpation showed tenderness in the right iliac fossa; the McBurney's point was very tender. The other systems were normal. Examination per rectum showed the presence of internal hæmorrhoids. Examination per vaginam was not done. The laboratory investigations were all negative. She was diagnosed as a case of 'chronic appendicitis'. At the operation, the appendix appeared pathological and was removed. The right ovary showed the presence of a solid mass about the size of a small orange and this was excised as well.

The specimens.—The appendix measured 5 cm. in length. The surface showed a few congested blood vessels but there was no exudate, or adherent fibrous tags. On cutting, the walls were thickened. The mucosa appeared swollen. There was no hyperæmia of the mucosa but pinpoint ulceration could be made out at many places. The lumen was patent and there was no fæcolith. The histological study showed the features of 'chronic appendicitis'.

The ovarian mass (figure 1, plate XIII) weighed 65 gm. and measured $6 \times 5 \times 4$ cm. in the largest diameters. It formed a well-circumscribed mass with the external surface rough and nodular. The consistency was firm. On cutting no distinct capsule could be made out. Trabeculae of fibrous tissue could be seen running all over enclosing irregular lobules of greyish yellow tissue. In the centre the fibrous tissue was more condensed and here the cut surface had assumed a whorled pattern. The whole surface was pale and avascular. Careful examination showed a few very tiny mucoid-looking areas. No definite cystic excavations could be identified. Histologically (figure 2, plate XIII), nests of epithelial cells surrounded by whorls of fibrous tissue could be seen all over the section. The epithelial islets varied in size and shape. In general, the cells composing them were polyhedral or oval with pale vacuolated cytoplasm. The nuclei of these cells were oval and vesicular, with a definite nuclear membrane, and possessed darker violet nucleoli; there was no hyperchromatism and no mitotic figures could be identified. Some of the cell groups were solid; others showed degenerative changes in their centres. In these latter the centres appeared empty except for a little

cellular detritus and were lined by cuboidal or flattened epithelium. Or, the central cells were distended and their nuclei lost; the cytoplasm of such cells appeared thin and translucent. In other cells the cytoplasm formed dense pink round bodies discarded from the cell wall. Some of these cell groups with marked liquefactive changes mimicked glandular patterns. In other portions the cells formed dense compact masses; here the cells appeared compressed and had assumed a columnar shape. Nowhere could be seen typical columnar cells of the goblet type with basal nuclei. The stroma was moderately cellular and was disposed to form whorls. It was condensed round the epithelial islets; quite frequently the stroma appeared as if it had formed a basement membrane to the epithelial cell groups. The stroma was avascular. As judged by the nuclear appearance the stroma cells were not highly proliferative. Hyaline degeneration could be made out in many places.

Case 2 (T/2033).—Brenner tumour in the wall of a serous cystadenoma.

Clinical history.—A Hindu female, aged 40, was admitted for a swelling in the abdomen—duration two years. The complaint started insidiously. About two years ago she had noticed, for the first time, a bulging of the lower part of her abdomen on the right side. There was no pain. The swelling had gradually increased in size to spread beyond the midline to the other side. There was no other abdominal disturbance. For the last six months she was getting irregular small rises of temperature off and on. Her menarche had started at the age of fourteen. The periods had always been regular, painless and the flow moderate in the amount. For the last two years the periods had become scanty and irregular, coming on every five or six months. The obstetrical history revealed a single normal delivery, eighteen years ago. There was nothing to note in the family history.

Examination showed the patient to be fairly well built and well nourished. Temperature 98°; pulse 80; respiration 22. Examination of the abdomen showed the presence of an intra-abdominal mass occupying the hypogastric and the iliac regions on both the sides and the lumbar regions on the right side. It was irregular in shape, and measured about 15 × 10 cm., with the greater part of its bulk on the right side of the midline. The consistency was elastic. It appeared to arise from the pelvis and was immobile in both the horizontal and the vertical directions. The swelling gave a dull note on percussion. The skin over the swelling was stretched but quite free. Examination per vaginum showed a small retroverted uterus quite apart from the abdominal mass. The latter appeared to be arising from the right ovary. There was nothing relevant to note in the laboratory investigations. At the operation, the mass was cystic and appeared to be in connection with the broad ligament on the

right side. It was excised without difficulty. The left ovary was normal and the peritoneal cavity did not contain any free fluid.

The specimen.—The mass (figure 3, plate XIII) weighed 2,670 gm. and measured 23 × 16 × 13 cm. The external surface was smooth and showed the stretched fallopian tube. There were a few prominent subcapsular veins but no papilliferous excrescences. The consistency was cystic all over except at one portion; here could be felt some elasticity and nodularity confined over an area of about 4 cm. in diameter. On cutting open the cyst was multilocular; the contents were serous fluid. The inner lining was smooth, and glistening except for a few raised patches greyish yellow in colour here and there (? lipoid deposits). There were no papillary excrescences. At one place in the wall was an oval nodule measuring about 4 × 2.5 cm. On cutting, the nodule appeared situated in the wall of the cyst. Its cut surface was greyish yellow and homogeneous. There was no naked-eye evidence of any cystic degeneration. Blocks were prepared from various portions of the cyst wall and also from the solid nodule. Histologically, sections from the wall of the cyst showed the structure of a serous cystadenoma (figure 4, plate XIII). This was separated from the Brenner nodule by a distinct band of connective tissue all round (figure 5, plate XIII). The Brenner tumour component had a structure similar to the one in the first case (figure 6, plate XIII). The central liquefaction was, however, more marked, producing many small cysts lined by a varying number of cell layers. Towards the centre again—away from the lining wall of the serous cystadenoma—the epithelial cell groups were more solid and here the cells tended to become squamous and a pavement effect was well seen. Nowhere could be seen any transition to goblet cells. The stroma appeared less cellular and less condensed than in the first case. Limiting the Brenner nodule on the other side—the side away from the serous cystadenoma—was compact ovarian stroma.

Comment

Brenner tumour by itself is an uncommon entity. About 30 per cent of the Brenner tumours appear as solid nodules in the walls of pseudo-mucinous cyst (Dockerty, *loc. cit.*). Their occurrence as solid nodule in the walls of serous cystadenomas is extremely rare. Frankl (1927) and Szathmáry (1933) have reported one case each. Novak and Jones (1939) did not find a single case in their large series and Dockerty and MacCarty (1939) had the same experience. On the other hand, Meyer (quoted by Novak, 1940) suggested that, like the pseudo-mucinous cystadenoma, serous cystadenoma may at times have its origin from the Brenner tumour.

I thank Professor R. G. Dhayagude for the permission to publish this paper.

INCLUSION BODIES IN RICKETTSIA ORIENTALIS INFECTION

By S. LAL KALRA

MAJOR, I.M.S./I.A.M.C.

Field Typhus Research, Dett., Jalahalli

THE observations of homogeneous, intracellular inclusion bodies in association with *Rickettsia orientalis* were made during an investigation of scrub typhus in Imphal in 1945 and were submitted in reports to GHQ(I). Twenty-five strains of *R. orientalis* were isolated from different sources. Similar observations have been made by Giroud and Panthier (1942) and Begg and others (1944) in association with classical typhus during the adaptation of mouse lung material to the lungs of rabbits.

When infected blood from patients or tissue material from mites or rats was inoculated in mice by intraperitoneal route in the first one or more passages the peritoneal exudate was thin, serous and abundant. In subsequent generations as the strain was established in the animal, the peritoneal exudate became sticky and very much reduced in quantity. During

this early stage of adaptation of *R. orientalis* to the new host, the following microscopic picture was observed in some of the animals, in the peritoneal smears stained with Giemsa stain.

The cytoplasm of the epithelial cells was extensively vacuolated and in some cells the vacuolation was present in the nucleus also. Some of the cells presented a distended appearance with vacuoles of various sizes and the nucleus pushed to one side. The majority of the vacuoles were filled with a homogeneous light pink material. Red inclusion bodies of various sizes and forms, but generally round and homogeneous in appearance, were scattered in the vacuoles and the cytoplasm. In some of the monocytes the inclusion bodies were present without any evidence of the vacuolation of the cytoplasm.

In the beginning the vacuolation was more extensive but the inclusion bodies were few. As passage proceeded, first there was an increasing number of inclusion bodies and a few typical rickettsia, later, the number of rickettsia increased, which appeared scattered at random in the cytoplasm of the cell, and the inclusion bodies became rarer. When the strain was well established fairly large clusters of rickettsia were present in the cytoplasm, and the peritoneal exudate was always sticky. But even at this stage the smears from the pleura showed a few inclusion bodies.

The above change from one stage to the other was generally gradual but sometimes sudden and occasionally a mouse even in 8th or 9th passage showed inclusion bodies. It was considered that this may be due to the use of mixed farm mice instead of the single strain breed. In order to verify it, WZ strain from Kalewa which was established in these mice was transferred in its 7th passage to Welcome mice, at the same time continued in the mixed farm. The first passage Welcome mice died after 16 days. The rickettsia were rare in the peritoneal smears, but there was marked vacuolation of the cytoplasm of the epithelial cells and inclusion bodies were present. The mixed farm mice passaged at the same time did not show any inclusion bodies and died after 12 days.

The second generation of Welcome mice died after 22 days and inclusion bodies though less were still present. In the third generation clusters of typical rickettsia appeared.

Later on the original stock of mice was exhausted and 8 strains that were being maintained for further experiments were passaged in a fresh batch of mice of unknown breed. Although the strains were by now established in mice the inclusion bodies appeared again but in very few animals and only for one generation.

The above picture was not presented by every strain, rather the majority of the strains showed typical rickettsia in the very first animal inoculated.

In guinea-pigs, the inclusion bodies were observed only in one animal inoculated with

tissues of bandicoots from Paungde in Burma. The other reactions observed in some of the animals were a marked preponderance of small lymphocytes in the peritoneal smears and the presence of mast cells of the cuboidal type. The rickettsia in these cases were generally typical though less in numbers and inclusion bodies were absent.

Summary

The inclusion bodies are considered to be a phase in the developmental cycle of *R. orientalis* during the stage of adaptation to a new host, but are characteristic of a few strains only.

CIRRHOSIS OF THE LIVER IN THE ADULT*

By P. V. GHARPURE, M.D.
(Grant Medical College, Bombay)

I PROPOSE to place before you an account of a few of my observations and those of others on the subject with a view to discussing the problem of cirrhosis of the liver and making out a case for planned investigation.

The subject of cirrhosis has been one of the prominent topics taken up by research workers for at least over a century. Work in India has been comparatively recent, but it has been very valuable. Much work is in progress in connection with infantile cirrhosis. Work on the adult type of cirrhosis also is in progress in India and outside India. This note is pointedly on cirrhosis in the adult. No reference to clinical and experimental work on infantile cirrhosis will be made considering that as a distinct entity. I am however not prepared to say that the result of researches on infantile cirrhosis will not be able to elucidate some problems of cirrhosis in the adult.

Definition.—There will be little to gain by introducing two different terms, cirrhosis and sclerosis, as such a grouping may make the confusion worse confounded. Ramchandra Rao (Rao and Radhakrishna Rao, 1938) suggested the two groups—cirrhosis and sclerosis; but some critics who followed him have not favoured this grouping.

For the present discussion let me then use the single term cirrhosis to embrace all conditions of the liver where fibrous tissue develops in excess, involving a very wide range of factors proved or not proved to be concerned in the completed picture of the cirrhosis, keeping out the gummatous or syphilitic livers and livers in

decompensated cardiac conditions, and possibly a few other conditions.

Literature.—On cirrhosis in the adult are summarized below in brief the contributions by workers in India in chronological order.

Hughes (1933) mentions 241 cases of cirrhosis of liver among 7,911 admissions to medical wards between 1929 to 1932 in the Punjab. He reviews 30 cases of fully established portal or multilobular cirrhosis; three of these had died in hospital and autopsy had been performed on only two. Special stress is laid on the part played by malaria in the causation of the condition.

Radhakrishna Rao (1933), following up his work singly and with Tirumurti on ascites in South India, presents a detailed clinical study of 64 cases, two of which were verified at operation and 12 at autopsy, all these cases were associated with ascites and were called by the author decompensated portal cirrhosis. In addition to this the author presents analyses of 21 cases without ascites. Without reproducing the figures of analysis I may say that the series embraces a wide range of conditions such as gummatous hepatitis and splenic anaemia. The age incidence of these 64 cases shows the highest incidence between 30 and 40.

Bhaskara Menon and Annamalai (1935) give an account of incidence of hepatic cirrhosis in South India. In this analysis the highest incidence is in the age group 30 to 40. The incidence of cirrhosis of liver as worked out from autopsy figures has been stated as 4.39 per cent. This paper refers to work on non-alcoholic cirrhosis in India and quotes Tucker (1908) ascribing it to malarial infection and Rogers ascribing it to amoebiasis possibly. The paper contains an interesting discussion on the origin and nature of the fibrosis.

Tirumurti and Radhakrishna Rao (1936) present a study of livers with a view to determining the rôle of malaria in causation of cirrhosis of the liver. They conclude that *per se* malaria is not a direct cause of the cirrhosis of the liver.

In all the above references the title cirrhosis has been used as an omnibus one, embracing all conditions wherein the liver is the seat of fibrosis. Few attempts have been made to throw light on aetiology or genesis of cirrhosis.

Radhakrishna Rao (1936) gives his findings on cirrhosis of liver following chronic intoxication with carbon tetrachloride using rats, rabbits and guinea-pigs as experimental animals. The findings are interesting.

Tyagaraja (1937) has discussed the early pathological changes in the liver in the tropics with special reference to cirrhosis. This study is based on 73 livers.

Incidence.—Incidence of cirrhosis of liver has been variously worked out. Rogers (Rogers and Megaw, 1930) states it as 6.9 per cent for Bengal, Tirumurti and Radhakrishna Rao (1934) 9.3 per cent for Vizagapatam, South India, Bonne

* A paper presented at the 34th. Indian Science Congress, January 1947, Delhi.

et al. (1931) 6.9 per cent and 5.8 per cent for Dutch East Indies, Tyagaraja (1937) 5.6 per cent for Ceylon and Gharpure (1928) 2.01 per cent for Bombay. The concluding remarks in the last paper were: 'Thus from the records available here much light cannot be thrown on any newer conception of cirrhosis of the liver'. To-day nearly eighteen years since these lines were written the position has remained unaltered at least to me.

Hall and Morgan (1939) give an account of 68 autopsies of confirmed cases of cirrhosis of liver from 13,000 autopsies. Jaundice was noted in 50 per cent of the cases, ascites in 60.3 per cent, hæmorrhage in 30.3 per cent and fatal hæmorrhage in 20 per cent. Correct clinical diagnosis was made in 36 cases or 52.9 per cent. Weight of the liver—highest 2,760 grammes, smallest liver 1,400 grammes. Spleen average weight 360 grammes (double the weight of the normal approximately). Liver smooth to granular in 40 (61.5 per cent), roughly granular nodular in 25 (38 per cent). Histology—relative fibrosis slight in 3, moderate in 14, marked in 32, extreme in 19. All the cases in which the W.R. was positive fell in the last two groups. Fibrosis was mainly periportal and was classified as cellular, moderately cellular and firm fibroblastic. Cellular infiltration of the periportal connective tissue has been noted and also necrosis of the liver cells and fatty infiltration noted. The ætiological factors are discussed.

In a series of 10,000 autopsies examined by me there is a total of 226 cases in which the liver has been the seat of cirrhosis, including one of infantile cirrhosis. There are two cases of cardiac cirrhosis in congestive cardiac failure. In the whole series 21 cases of congestive cardiac failure have been recorded and cardiac cirrhosis occurred only twice in them. I am therefore not inclined to separate these two cases as a distinct group. Of the 225 cases, 23 are associated with ulcers in the colon, all declared on anatomical ground as amœbic. There is a total of 1,164 cases of dysentery in the whole series. Of these 54 are bacillary, acute and chronic. Bacillary dysentery was diagnosed for the first time only in 1907 and the cases of this series commenced from the beginning of 1882 and ended on 9th July, 1945. Of the 1,110 cases of amœbiasis, 44 are chronic showing thickening of the bowel, strictures, healing, etc., 23 of these, *i.e.* over 50 per cent, have cirrhosis of the liver. Thus the rôle of amœbiasis in relation to cirrhosis of the liver needs consideration. As regards the relation of malaria to cirrhosis my findings do not indicate a direct relationship. There are only four cases wherein these two conditions co-exist. Kala-azar has been recorded twice associated with cirrhosis. However, I am not qualified to speak on this subject, this part of India not being an endemic area. There are 13 cases of gummatous or other kinds of syphilitic livers, and one each of cholecystitis and of carcinoma of ampulæ of Vater. There

are left 178 cases of cirrhosis with no causative agent that one can even surmise. Incidence of the bulk is 2.25 per cent and of the selected ones 1.79 per cent. At least judged from post-mortem data, cirrhosis of the liver is not such a frequent condition in Bombay.

Associated infections, etc. :—

Ulcers, intestine	23
Abscess, liver	2
Peritonitis	2
Pneumonia	1
Congestive cardiac failure	2
Bronchiectasis	1
Arteriosclerosis	1
Renal dwarfism	1
Tuberculosis lung	9
Carcinoma pancreas	1
Chronic gastritis	1
Cholecystitis	1
Kala-azar	2
Malaria	4
Syphilis	13
Carcinoma liver	5
			<hr/> 69

Other findings :—

Ascites	35
Jaundice	11
Hæmorrhage	6
Ascites and jaundice	3
Pleural effusion	3
Pericardial effusion	2
			<hr/> 60

Age incidence :—

11-20	26
21-30	66
31-40	55
41-50	33
51-60	18
61-70	6
71-80	3
Unrecorded	18
			<hr/> 225

In 18 cases age has not been recorded, but the body has been described as that of an adult male or female. If the figure is included in age groups 21-40 then a total of 139 cases occur between 21-40. One meaning of a late age can be a protracted course of development of the fatal picture of cirrhosis.

Sex incidence.—There are 23 female cases in the group of 225.

Weight of the liver.—Standard weight for an adult is taken as 1.2 to 1.6 kg., or 1/36th of the body weight. Lowest weight recorded is 210 mg. in a male aged 65 and the highest 4,550 gm. in a male aged 32. Weights have not been recorded in 123 cases.

Under 600 gm.	..	6
Between 600 and 1,200 gm.	..	69
Between 1,200 and 1,600 gm.	..	19
Between 1,700 and 2,200 gm.	..	7
Above 2,200 gm.	..	1
		<hr/> 102

Small livers are comparatively few. The body weights have not been recorded in all cases, hence no attempt is made to work out the ratio, liver to body weight.

Weight of the spleen.—The upper limit of a normal spleen is taken as 150 gm. and spleens weighing 180 and above are called enlarged.

Up to 600 gm.	..	61
Between 600 and 1,200 gm.	..	16
Between 1,200 and 1,800 gm.	..	6
		<hr/> 83

The highest is 1,750 gm. In 19 cases of cirrhosis of the liver the spleen has not been enlarged and weights have been between 50 gm. and 150 gm.

The weight of the spleen does not appear to bear an inverse relation to that of the liver. Cases in which the spleen weight is below 150 gm. the liver weights have been 700 to 1,000 gm. It is more probable that splenomegaly is marked when the liver has not undergone extreme reduction in size.

Degree of fibrosis.—The histological picture falls in one of the following three general groups (excluding gummatous livers):—

1. Necrosis of groups of cells with little, moderate to extreme fibrosis.

2. Universal fatty metamorphosis of cells and marked to extreme fibrosis.

3. Fairly well preserved cells with inflammatory cell infiltration interrupting the pattern.

In 1 and 2 the livers are small and in 3 they tend to be large. In my opinion much cannot be gained by classifying it as slight, moderate, excessive, extreme, etc. What is more useful is to correlate the extent of the damage to the liver cells. The extent of cell infiltration in the portal tract or around lobules or within the lobule is more helpful. Tyagaraja (1937) has given an interesting account of such livers. In all these there is no cirrhosis and the damage to liver cells minimal if at all. Could these conditions be precursors to cirrhosis? Then there are two problems—(1) beginning with hepatitis (interstitial) and (2) beginning with necrosis of liver parenchyma and degeneration of the cells.

Morbid anatomy studies with post-mortem material have not been helpful.

A few dozen biopsies have been studied in this institution such as those that have shown the histology of one single phase in the history of a diseased liver. My colleague, Dr. J. G. Parekh, has been obtaining these biopsies whenever possible. This has not been helpful beyond diagnosing an occasional case.

Nine recent autopsies done by me in cases of infective hepatitis showed some degree of replacement fibrosis and necrosis of the liver parenchyma. In the autopsy records in my department there are 23 post mortems on cases of subacute atrophy of the liver. In these again varying degree of developed fibrous tissue is visible. These two groups may be similar if not the same.

To connect the histology in fibrosis and its antecedent conditions a few facts regarding the structure of the liver may be noted here.

1. The liver cells on the one hand and the endothelial and kupffer cells on the other are separated by a delicate collection of collagen layer. This area shows an occasional fibroblast and lymphocytes. It is the collagen layer that gets separated in serous hepatitis. This is considered to be an evidence of the mildest degree of damage to the liver.

2. The portal canal is a connective tissue structure with a collection of lymphocytes, mononuclear cells and fibroblasts. This is poor in collagen. The cell and collagen content increases with age. The above two have an important bearing in interpreting the early histological changes toxic or otherwise.

Injurious agents are of two types—(1) soluble in blood and (2) insoluble in blood, and the routes by which they reach the liver are varied. They may be by portal vein, hepatic artery or bile ducts, hence the nature of the damage varies. Necrosis as it is noticed, therefore, can be focal, zonal, central, mid-zonal, and peripheral.

The focal necrosis is explained to some extent by Mallory as a combined effect of the wandering cell emboli and bacterial poison. The zonal necrosis briefly stated is not satisfactorily explained—two suggestions are put forward. Selective actions of hepatic cells and possible difference in the functions of cells anatomically classified central, mid-zonal and peripheral.

A brief summary of the causal factors is as follows:—

1. Alcohol addicts 5 to 6 per cent develop cirrhosis. 25 to 35 per cent cases of cirrhosis give history of alcoholism.

2. Deficiency of dietary constituents—carbohydrates, vitamin B, choline and protein.

3. Infections.

4. Hepato-toxic agents.

No single agent is responsible for the complete picture of cirrhosis. The rôle of formation of fibrous tissue and sequence in which it occurs require a careful study. Is it a phenomenon subsequent to the action of a number of factors acting concurrently or in succession producing damage? Then all fibrosis in the liver is a replacement fibrosis.

Is there anything like interstitial hepatitis in the absence of damage to liver cells?

What are the factors responsible and may not these necessarily be causal factors for fibrosis and for the progressive destruction of liver cells?

Are there two distinct groups—(a) factors that lower the resistance of cells and (b) factors that attack the vulnerable cells and effect necrosis—the antecedent to replacement fibrosis?

Thus the problem becomes complex but a rational plan of investigation is possible, detection of damage to cell from its initial stage and through the evolution of the condition, progressive or regressive, by (i) Chemical test—hippuric acid synthesis test suggests itself. The normal synthesis is said to require the whole intact liver. (ii) Bacteriological study. (iii) Histological study by repeated biopsies.

The few experiments done by my colleagues in my laboratory attempting to produce cirrhosis have failed, maybe due to our technical defects. Vacuolation of liver cells comparable to fatty changes has been produced but not cirrhosis. Animal experiments may be very interesting but the all important question will arise in the end: Can the findings be applicable to the disease condition—or process as it occurs in man? Hence my plea for intensifying clinical research. The understanding of the subject of cirrhosis will only be possible if repeated efficiency tests and repeated biopsies were possible and undertaken over a reasonable period in addition to critical clinical study.

Since my writing this note a very interesting paper by Dr. P. N. Wahi, M.D., M.R.C.P., on Study of Liver Disease has appeared in the *Indian Medical Gazette*, Vol. LXXXI, No. 11, November 1946.

SCRUB TYPHUS IN NORTH BURMA

By D. J. REDDY
 CAPTAIN, I.M.S./I.A.M.C.

NEARLY 100 cases of scrub typhus were treated in an Indian General Hospital at Meiktila from May to November 1946. Peak of admission

rate was noticed in August and November. A rise in the incidence of scrub typhus had been noticed a fortnight after a heavy shower of rain. Vast stretches of uncultivated land filled with scrubs and wild grass is a feature of Meiktila and places round about. The incidence amongst the Burmese, Indians and Japanese troops was equal although proportionally there had been a low incidence amongst British troops, which might be due to less troop movements and avoidance of scrub, etc. The disease was mild amongst Burmese, of moderate severity in Indian and most severe amongst British troops.

Incubation period.—It was not possible to determine it as we could procure neither the history, nature, time of the mite bite nor the associated troop movements. The patients came under hospital care on the fourth or fifth day of fever.

Age incidence.—Majority were between 20 and 30 years though a few occupied the lower limit of 20, and very few, if any, at or above 40.

Nature of fever.—Patients were referred to the hospital on the fourth day of fever. Severe headache and pain in the lower limbs was a common complaint. The initial rise of temperature was usually in the region of 102°F. and 103°F., and the fever remained remittent with daily remission of 1 to 1.5°F. The highest temperature recorded during the course of the disease was 104°F. The febrile period was between a minimum of 12 days and maximum of 26 days, though the majority had temperature only for 18 to 20 days. In a few, the temperature lasted up to 40 days, in whom invariably secondary bronchitis was the prolonging factor. The temperature chart during the first and early part of the second week of fever had not the slightest resemblance to that confronted in typhoid (step-ladder like). The temperature touched normal by lysis and on an average took four days to do so. With the temperature touching normal the patient was on the road to uneventful convalescence, and complete recovery. No recrudescence of fever was noticed. A small percentage of cases had malaria to start with which showed appropriate alterations in the temperature. The temperature in these cases did not abate on antimalarial treatment. Majority of them had bronchitis to start with though a few developed it during the third week of illness. One patient had a pneumonic onset of fever with cyanosis, hurried respirations and positive chest signs.

Pulse.—On an average the maximum recorded pulse at the height of fever was between 100 and 110 per minute, bradycardia in comparison to temperature, but was not dicrotic. The blood pressure was taken during the second week of illness, systolic was between 100 and 110 mm. Hg. and diastolic 50 to 70 mm. Hg.

Main symptoms and signs.—The facial expression of the patient at the end of first week of fever was highly characteristic being dull and lethargic. All of them looked doped, with

eyelids half closed. Patient could be hardly roused, cerebation was slow and hands were tremulous. The tongue was dry and coated (dehydration). A small percentage exhibited a low muttering delirium at the end of first week of illness. Asthenia was a prominent feature.

The abdomen was soft and yielding. The bowels were constipated. The spleen was palpable in many, though no importance could be attached, as most of them had suffered from malaria.

Eschar.—Often noticeable by the sixth day of fever as a circular moist ulcer which healed by leaving a black scar of 1 cm. diameter and dropped off during convalescence, leaving no marks behind. Serotal, inguinal and axillary eschars were most frequent, though in a few typical ones were located in pre-auricular region and pit of stomach. About 40 per cent of the cases only showed the eschar.

Adenopathy.—Lymphatic glands draining the eschar were always enlarged, discrete, soft and tender. They were usually of peanut size ($\frac{3}{4}$ inch diameter), marble size was sometimes reached as was seen in the case of a pre-auricular eschar. Regional adenopathy was followed by generalized adenopathy in a couple of days, the cervical and inguinal chains being the most common. Generalized enlargement of glands was noticed in cases showing no eschar. The glands retrogressed and were not palpable at the close of convalescence.

Rash.—Rash was never observed in the Indian troops. Macular type of rash was seen in two British and one Japanese patients. Rash was observed in a Burmese, distributed over the face, chest, abdomen, and flexor surface of limbs and was mistaken for measles. Rash was observed at the end of first week of illness.

Deafness.—Deafness was complained of by majority of patients on the tenth day of fever, quite marked in some. It cleared up with the onset of convalescence.

Laboratory data.—1. In 31 per cent of patients the total leucocyte count was between 4,000 and 5,000 whilst in the remaining it was up to 10,000 per c.mm. In very small percentage of the latter group a total count of 18,000 was recorded. They had either a superimposed bronchitis or broneho-pneumonia. Lymphocytes ranged between 40 and 46 per cent of the total leucocytes and were of mature type.

2. Blood and urine cultures carried out during the febrile period were sterile and no pathogens were isolated from stool cultures.

3. Blood sedimentation rate was raised 60 mm. at the end of first hour (Westergren method) during the active phase of disease and early part of convalescence. Returned to normal after nearly two months of convalescence.

4. C.S.F.: No pathological changes were seen. Culture—sterile.

5. Serological findings:—

(a) Kahn tests, 15 per cent of them, were positive during the active phase of disease

which turned to negative during convalescence except in a few who had either been treated for syphilis or gave a history of having had a sore.

(b) Aldehyde and Chopra tests were negative in all of them.

(c) Widal and Weil-Felix reactions. During the first week of fever a titre of 1/160 to 1/320 in T₀ was observed in majority of cases which showed a decrement in the second and third weeks of fever when OXK began to show a diagnostic titre of 1/320 and above. There was no appreciable rise in OXK titre in the first and early part of second week of fever. A diagnostic titre of 1/320 to 1/640 was recorded between the 12th and 14th day of fever. Maximum titre of 1/5120 to 1/20480 was recorded either at the beginning of third week of disease or early in convalescence. OX19 and OX2 did not rise above 1/40 in most of the cases. In extremely toxic cases the diagnostic titre was not obtained till late in the disease and these cases gave the highest titre in convalescence (1/20480). An OXK titre of 1/320 (Felix method) and above either in the course of the disease or during convalescence was taken as the diagnostic titre. A titre of OXK below 1/320 was recorded in fevers other than scrub typhus. One amongst the lot had been inoculated against scrub typhus. He had a mild attack and agglutinins against OXK did not rise over 1/320.

It is worth while to point out that sera of persons inoculated against scrub typhus tested against OX2, OX19 and OXK suspensions weekly for two months after the last prophylactic dose gave a maximum titre of 1/40. We had trouble with OXK suspensions as they were unstable. Periodical checking of the suspensions against negative and positive sera could only overcome this difficulty. Turbid and brownish suspensions are to be discarded.

Complications.—Two cases simulated acute abdominal conditions like subphrenic and appendicular abscesses. Some developed broncho-pneumonia. Fifteen per cent had malaria to start with. The most fatal complication noticed was hiccough in three patients who succumbed to it. The hiccough was of toxic origin as P.M. examination showed neither dilatation of stomach nor peritoneal involvement. Their blood urea was within normal limits.

Sequelae.—Patients were extremely asthenic. They had a ravenous appetite. Convalescence was uneventful and patients put on considerable weight. Only one developed (Adi Kundu) peripheral neuritis and his convalescence was prolonged. The temperature in his case had touched normal on the 42nd day.

Mortality.—There were three deaths due to scrub typhus during the six months which worked out at 4 per cent.

Diagnosis.—During the first week of fever scrub typhus had to be distinguished from typhoid, salmonella fevers, measles, septicæmia,

(1)

(3)

(4)

*None in Indians.

† Bronchitis excluded.

† Diagnostic titre

subacute bacterial endocarditis and cerebro-spinal fever. The presence of a typical eschar with regional and general adenopathy, the characteristic doped look of the patient with eyelids half closed, a normal leucocyte count or a leucopænia with relative increase of lymphocytes associated with sterile blood, urine and C.S.F. cultures are highly suspicious of scrub typhus in an endemic area. Sometimes general adenopathy with rash was confused with secondary syphilis. The glands are tender and Kahn test negative in typhus (Japanese). Diagnosis is usually confirmed in the second week by the appearance of diagnostic titre in OXK in the serum of the patient. A rising OXK titre had been accepted as diagnostic.

Treatment.—Efficient nursing had reduced the mortality rate to a great extent. Attempts to dilute the toxins and prevent dehydration by intra-gastric and intravenous drips of glucose saline had saved the lives of many. Fresh lime juice and multivitamin tablets were given as a routine. Penicillin and sulphonamide drugs were tried with no benefit, except when complicated by broncho-pneumonia (in the case of Errington). Hiccough developing in the third week of fever does not respond to symptomatic treatment.

Histological picture.—One of the autopsy cases is outlined below :—

Lymph gland.—Congested. The endothelial lining of the sinuses was swollen and desquamated. Numerous large mononuclear phagocytes could be seen.

Heart.—Muscle fibres were swollen and structureless with evidence of fragmentation. Considerable oedema present. Fair degree of diffuse infiltration of round and plasma cells seen, occasionally being perivascular. Subpericardial round cell infiltration noticed.

Lungs.—Marked hyperæmia of the alveolar capillaries with hæmorrhages into the alveoli. Many pigmented macrophages seen. The alveolar septa are thickened by oedema, congestion and inflammatory cells. Capillary hæmorrhages were observed.

Liver.—Columns of liver cells swollen, granular, with vacuolation in central zones. Marked round cell infiltration seen in the portal tracts, not perivascular in distribution, extending between liver cords.

Kidneys.—Marked hyperæmia of the glomeruli and inter-tubular capillaries seen. The glomeruli were swollen and more cellular than normal. The tubular epithelium showed degenerative changes, being swollen and granular. The lumina contained albuminous debris.

Cerebrum.—Generalized capillary congestion and marked oedema noticed. Focal collections of mononuclears, lymphocytes, some glial cells, mostly perivascular, seen in the subcortical white matter. General increase in cellularity of mononuclears and lymphocytes seen.

A tabulated chart containing main clinical and serological features seen in 68 scrub typhus patients is included.

My thanks are due to Colonel A. M. Chaudhury for his encouragement and to my laboratory staff who had ungrudgingly helped me in carrying out the necessary investigations.

TREATMENT OF TYPHOID FEVER WITH PENICILLIN*

By U. P. BASU, M.B., F.R.C.P.I., F.S.M.F.

*Late Principal and Professor of Clinical Medicine,
Calcutta Medical College*

BETWEEN October 1945 and November 1946 my opinion was requested in the treatment of seven critical cases of enteric fever under the grip of severe septicæmia. Of these 4 were Hindus, 2 Muslims and one Indian Christian. Five belonged to the male and two to the female sex. The ages of the male patients ranged between 16 and 40 years and of the female patients one was aged 18 and the other 25. All of them were seen between the 3rd and 4th week of illness. Widal reaction was positive in all of them; O agglutination 1 in 125.

In all these cases the pyrexia varied between 104°F. and 105.4°F. They were all in the stage of coma vigil—unconscious with eyes half open having low muttering delirium. There was carphology and subsultus tendinum. Their tongue was coated with heavy creamish white fur, the tip and borders of which were angry looking. Their pulse rates were between 140 and 150 and rates of respiration between 34 to 44 per minute. Their conjunctivæ were injected—their abdomen tumid and they were all passing liquid stools 4 or 5 times and urine 3 or 4 times a day involuntarily in bed. Before I was called in they were having hydrotherapy, phage and vitamins internally and 25 per cent glucose intravenously 50 or 100 c.c. daily according to the needs of the cases.

Unfortunately in all these cases with this line of treatment there was no improvement. Obviously I was consulted to suggest some remedy that might prove effective and check the course of the illness.

The first of this series was a Hindu girl aged 18 years. In addition to the signs and symptoms described above she had bronchitis with a W.B.C. count of 7,000 per c.mm. and neutrophils 76 per cent. There was slight normocytic hypochromic anæmia. As the patient had bronchitis, I tentatively advised 30,000 units of penicillin intramuscularly every 3 hours just to watch its effect on the bronchial tubes. I was agreeably surprised to find that by the time 90,000 units of penicillin were injected the delirium was replaced by sound sleep and there appeared droplets of perspiration like dew-drops

* Being a paper read before the British Medical Association, Calcutta Branch, in December 1946.

all over the forehead. The temperature also was one degree less. There was not much improvement about the condition of the bronchial tubes at this stage. This line of treatment was therefore continued and the fever broke by crisis. The temperature became subnormal after she had received 300,000 units of penicillin. The facies of the patient remarkably improved and her general condition became better. She talked coherently and the bronchitis disappeared. Penicillin was therefore discontinued. The temperature remained normal for 18 hours and then gradually started rising till it reached 101° in the course of next 12 hours and then fluctuated between 101°F. and 100°F. for a day. Further injections of 210,000 units of penicillin in same dose and same interval were given as before. Within 24 hours the temperature became subnormal and the patient entered into convalescence. Thenceforward the disease disappeared leaving only one complaint, *viz*, moderate tympanitis. It took about a fortnight for the tympanitis to disappear.

Encouraged by the good result of penicillin in this case, I advised the other patients of this series similar line of treatment with more or less identical results except in 2 cases. The first case was the last but one case of this series, a Hindu boy aged 16, who was seen by

Chart 1.—Case 1.

me on the 24th day of illness. The patient was restless and violent with meningismus. Lumbar puncture was done, fluid came out with pressure but in all other respects it was normal and culture showed no growth. In this case I suggested pushing in of penicillin by continuous intravenous drip method, failing which by the continuous intramuscular drip method. As neither of these methods was allowed by the patient's relations, I therefore advised as the last alternative high doses of penicillin. 60,000 units were administered intramuscularly every 3 hours. Altogether 660,000 units were given after which perfect convalescence was established. In this case also meteorism continued to trouble the patient for nearly a fortnight after which he was in all other respects completely normal.

The second case was the last case of this series, an Indian Christian girl aged 25, who developed broncho-pneumonia in the 3rd week

of enteric fever. Penicillin 60,000 units were given intramuscularly every three hours along with 100 c.c. of glucose, oxygen, strychnine, atropine, coramine, cardiazol, ephedrine, etc., but nothing was of any avail and she succumbed

Chart 2.—Case 6.

to peripheral circulatory failure on the 2nd day of penicillin treatment.

Commentary.—1. It is true *in vitro* it has been proved that penicillin is useless in destroying *Eberthella typhi* but in clinical practice as reported above it has been found successful in six out of a series of seven proved cases of typhoid infection. Obviously the number is far too small to warrant any opinion about the success of this drug in the treatment of typhoid fever. Nevertheless from the case reports it would appear that penicillin is well worth a trial in the treatment of enteric fever.

2. The continuance of distension of the abdomen after convalescence has been established is probably due to slow healing of ulcers in the Peyer's patches after quick defervescence. How the abdomen would behave if penicillin were administered early in the disease remains to be seen from future case reports.

3. It may be held that in the cases reported above the good result of penicillin was due to its action on secondary infection with other organisms for example *Streptococcus hemolyticus*. But it will be futile to argue in this vein as blood cultures in all these cases except in the first showed no growth of streptococcus or any other organism. In the first case blood culture was not done.

ISOLATION OF OESTRONE FROM THE URINE OF A CASE OF FEMINISM*

By E. G. MONTGOMERY, M.Sc., M.B., B.Ch., B.A.O.
LIEUTENANT-COLONEL, I.M.S.

and

P. DE, B.Sc., M.B. (Cal.), F.R.C.P. (Edin.), F.N.I.

From the Department of Physiology, Medical College, Calcutta

A REPORT on the biochemical investigations carried out by us on a case of feminism in a young adult male was published in the May 1947 issue of this journal. Part of this work included a study of the urinary steroid excretion.

* Read at the Physiology Section of the 34th Session of the Indian Science Congress held at Delhi in January 1947.

Owing to postwar difficulties it was not possible to obtain the special apparatus required for the estimation of 17 ketosteroids in accordance with the method described by Callow, Callow, Emmens and Stroud (1939). It was decided therefore to attempt a separation of the androgenous and oestrogenous material in urinary extracts by a process of selective adsorption on a column of calcium hydroxide. During these experiments oestrone was obtained in sufficient quantity to allow of its identification.

Biological estimation of the oestrogen activity in the crude extract indicated that this was in excess of the normally accepted levels.

Experimental

Urine was collected daily and removed every morning to the laboratory for extraction. During the collection in the ward decomposition was prevented by storing the samples on ice. Though the mean temperature was high (90°F.) the pH of the samples remained very constant and did not rise above pH 6 before hydrolysis.

The daily collections measuring between 1 and 1½ litres were hydrolysed in accordance with the method described by Callow, Callow, Emmens and Stroud (1939). Extraction with benzene was effected by means of a mechanical shaker, as a continuous extraction apparatus was not available. This gave rise to a troublesome emulsion at times, which however could be broken down by stirring and removal of the benzene by filtration.

170 c.c. of benzene extract, equivalent to 1,400 c.c. of urine, were put through a column of dry calcium hydroxide 25 cm. \times 1.5 cm.

When this had passed through, the following coloured zones were visible in the column, reading from top to bottom: dark brown, light brown, yellow and pink.

The filtrate, measuring 100 c.c., yielded only a yellow gum on evaporation.

The column was then developed with benzene, and successive portions of the elute evaporated. Fraction I, amounting to 90 c.c., yielded more yellow gummy material which was discarded.

Fraction II was still slightly coloured, but on evaporation gave a white amorphous deposit, mixed with traces of yellow gum. This was dissolved in 1 c.c. of methyl alcohol and allowed to stand. Fine needle-shaped crystals were deposited, but the amount was not sufficient for further investigation.

Fraction III 90 c.c. was a clear solution and gave a white amorphous material on evaporation. This was dissolved in 5 c.c. of methyl alcohol and set aside to crystallize. After 24 hours fine needle-shaped crystals were obtained. These were filtered off, redissolved in methyl alcohol, re-crystallized, and dried. The yield amounted to 1 mg.

By this time the pink zone had reached the bottom of the column, and further elution gave highly coloured fractions, which on evaporation yielded only dark red amorphous deposits.

Minute red crystals were obtained from these fractions when dissolved in, and allowed to crystallize from methyl alcohol. These appeared to be pigmentary substances and were not further investigated.

The material obtained from fraction III gave positive sterol tests. It had a melting point of 247°C., which suggested its identity with oestrone.

Biological tests on ovariectomized mice were carried out in accordance with the 4-injection method of Emmens (1939), control animals receiving a similar series of injections of a solution made up from a standard specimen of oestrone. Examination of vaginal smears gave 100 per cent positive results in both series.

Oestrogenic activity of the phenolic fraction from the crude extract was also estimated by the same method. The results indicated an activity of 500 I.U. per litre of urine.

Discussion

Oestrone is excreted in small amounts in normal male urine, and output may be increased by the injection of testosterone, or androsterone (Steinach and Kun, 1937). Testosterone also can increase the output of androsterone. Part of the oestrone excretion may therefore be due to the degradation of these two substances in the body.

It is not the only source, as investigations indicate that both androgen and oestrogen excretion are contributed to by the adrenal cortex (Callow, Callow and Emmens, 1940).

Hyperfunction or tumours of the cortex may be accompanied by large quantities of oestrogen or androgen in the urine, and in such cases it is interesting that such hyperfunction or tumour usually produces excessive amounts of the hormone considered normal to the heterogeneous sex. Thus virilism in the female is usually accompanied by a large output of androgen, and feminism—a much rarer syndrome—tends to produce excessive oestrogen.

The reason for this is obscure. Vines *et al.* (American Medical Association, 1942) consider that the adrenal is a potentially bisexual accessory gland capable of excreting androgen and oestrogen under appropriate stimulation of the pituitary. Others consider that owing to the disturbed metabolic function of the cortex, androgen and oestrogen are produced as by-products, or intermediate products, during the formation of adrenal hormones.

While the influence of the pituitary on the adrenals is undoubted, it is difficult to understand why this should lead to excessive production of oestrogen in one case, of androgen in another, and sometimes to an undue amount of both in the same individual.

It may be that there are in reality two adrenocorticotrophins, and Golla and Reiss (1942) are of this opinion. The experimental work of Davidson and Moon (1936), and Davidson (1937) is also highly suggestive. These observers have obtained androgenic effects in

castrated rats following the injection of adrenocorticotrophin free from gonadotrophin or growth hormone. Moon (1937) has also observed signs of œstrus in immature spayed rats after similar injections.

Hypophysectomy in animals leads to degeneration of the zona reticularis and fasciculata of the adrenal cortex. Injections of pituitary extracts free from gonadotrophins will prevent these changes. It is in these zones that fuchsinophil material can be demonstrated in cases of virilism by the staining reaction introduced by Broster and Vines (1933). Feminism is a much rarer syndrome, but in a recent case reported by Simpson and Joll (1938), the staining reaction was negative.

Anselmino, Hoffmann and Herold (1934) have shown that following the injection of adrenocorticotrophin there is an increase in the number and size of the cells in the glomerular and fascicular zones, and also an increase in their secretory activity.

It seems therefore that two adrenotrophic hormones exist, and that their influence is exerted on different layers of the adrenal cortex. Under these stimuli androgenous material is elaborated in the inner zones and œstrogens in the outer. The output of excessive androgen or œstrogen in pituitary dysfunction, or in cortical tumour formation, originates in the particular zone which happens to be overactive, or is the main seat of tumour formation.

The results we have obtained during our investigations of the case mentioned in the opening paragraph strongly suggest hyperactivity of the zona glomerulosa in this patient, which in all probability was the cause of the excessive excretion of œstrone in the urine.

Summary

1. The isolation of œstrone from the urine of a case of feminism by a process of selective adsorption is described.

2. It is suggested that pituitary adrenocorticotrophin consists of two factors, and that each exerts its effect on different zones of the adrenal cortex.

3. Androgen and œstrogen are elaborated in different zones, and excessive production of either results from the particular zone which is overactive, or is the main seat of tumour formation.

Our thanks are due to Professor P. Chatterjee of the Medical College Hospitals for facilities afforded in our investigations on this case, and to the assistants of the department for their help.

KALA-AZAR IN JAIPUR

By ROBERT HEILIG, M.D.

and

RAJ NARAIN SACHDEV, M.B., B.S.

Lady Willingdon Hospital, Jaipur

COMPARING the map of kala-azar distribution in the textbook of Napier (1943) with that given by Rogers and Megaw (1944), we find that the latter authors are showing some 'light incidence' reaching up to the south-east of Delhi, somewhere near Agra, while the former puts Lucknow as the westernmost point of kala-azar occurrence in Northern India. In 1937, however, 28 cases have been treated in the Punjab and 36 in Delhi (Annual Reports, 1939). Although this divergence points to some possible difference of opinion on the geographical distribution of kala-azar, all authors are agreed on 'its westerly extension being checked by the dry areas' (Napier, *loc. cit.*). Jaipur being well within these dry areas, the following report may be of some interest; it confirms the experience that wherever one looks for kala-azar, one shall find some.

Our way to the discovery of kala-azar among our patients was the experience that some cases of splenomegaly with more or less liver enlargement showed no response to antimalarial treatment, while Napier's aldehyde test, white blood picture, response to pentavalent antimony and the presence of Leishman-Donovan bodies in the sternal smear of two of them confirmed our provisional diagnosis of kala-azar.

The table shows the essential features of nine cases. We included those cases which showed a fully positive Napier's aldehyde test; doubtful reactions were discarded, so that we might have missed early cases of kala-azar, the aldehyde reaction taking about five months after the onset of clinical illness to become strongly positive. As neither trypanosomiasis nor schistosomiasis occur here, we seem justified in basing our diagnosis mainly on this test (*cf.* Napier, *loc. cit.*).

A considerable number of Leishman-Donovan bodies have been found in two (nos. 6 and 9) of our cases; they were scarce in one case (no. 8) so that the pathologist classified it as doubtful and not found in two cases, both of which had been under antimony treatment for some time prior to the sternal puncture.

Case no. 8, whose sternal marrow smear was described as doubtful as far as Leishman-Donovan bodies were concerned, presented such a classical picture of kala-azar (see table) that the diagnosis could hardly be doubted. With no other treatment but urea stibamine injections, his intermittent fever, which lasted for five months and in hospital reached 102°F. every day for 12 days, subsided completely after the third injection, i.e. after 0.325 gm. of urea stibamine; after 9 injections, making a total of 1.475 gm. urea stibamine, Napier's test was negative and after another 2.0 gm., two months after specific treatment was started, spleen and liver had regained normal size, leucopenia with lymphocytosis as well as anaemia were replaced by a normal blood picture, the sedimentation rate was reduced from 85/140 to 25/45. The patient, a tall man, was admitted with a body weight of 112 lb. and discharged with 131 lb.

In the two cases, whose sternal smear was negative for Leishman-Donovan bodies, the puncture was performed some time after specific treatment was started, because at this time we had no sternum puncture needle. One of them (no. 2) showed such a striking response to pentavalent antimony after everything else had failed that this alone, apart from all the other characteristic signs and symptoms, would establish the diagnosis beyond any possible doubt.

This young man was admitted with high remittent fever up to 105°F. which did not yield to the most intensive antimalarial therapy, including 5 intravenous quinine injections, and with profuse epistaxis which continued almost daily until hardly any hope seemed left to save his life; the second urea stibamine injection stopped fever and bleeding overnight. He regained health and a normal blood condition within four weeks.

Much time was lost in this case, even after the diagnosis was established, due to the impossibility of securing urea stibamine or stibatin locally, as no kala-azar ever was diagnosed in this part of the country, and the other antimony preparations, used here for the treatment of oriental sore, failed completely to give any relief. The other one (no. 1) whose sternal smear failed to show Leishman-Donovan bodies was complicated by a lymphocytic pleural effusion; Mantoux's tuberculin test was highly positive so that most probably a tuberculous pleurisy was present in addition. Here, again, every attempt failed to control his irregular high fever until urea stibamine injections were started.

All the other characteristic features of kala-azar, such as *splenomegaly*, *liver enlargement*, *leucopenia* with relative *lymphocytosis* (with the exception of no. 3 and, perhaps, no. 4), *hypochromic anaemia* and extremely *high sedimentation rate* of erythrocytes were present in all these cases. *Pigmentation* of a curious greenish-blackish tinge appeared in cases 1 and 9; no. 2 was fair, most of the others dark brown, showing no particular hue which could have led to the diagnosis.

Fever was recorded in five cases (nos. 1, 2, 6, 8 and 9) and two cases (nos. 4 and 5) were afebrile. One (no. 3) was afebrile but for two sudden rises of temperature up to 102°F. on consecutive days; malarial parasites were not found but the malaria flocculation test was ++ positive and the temperature subsided promptly with mepacrine. A further follow-up was not possible, the boy having been removed from hospital the moment he became afebrile. This case is peculiar for the co-existence of typical oriental sore, which promptly healed after 6 Pantorin injections, and a fully positive aldehyde test. It is well known that systemic kala-azar and oriental sore are very rarely found at the same place; the climatic conditions required by the respective transmitters being contrary to each other. *Phlebotomus argentipes*, the transmitter of the former, is an inhabitant of moist areas while *P. papatasi* and *P. sergenti*, which probably carry *Leishmania tropica*, the causal organism of cutaneous leishmaniasis, are found almost exclusively in dry climate with extreme temperatures such as the desert district of Jaipur State. But exceptions are known; kala-azar and oriental sore occur side by side in Crete and sporadic cases of both have been reported from Benares (cf. Napier, *loc. cit.*, p. 180).

The temperature of the febrile cases persisted, in spite of antimalarial treatment and every other therapeutic attempt to control it, including various antimony preparations, until urea stibamine was given; three to four doses of it brought down the high swinging temperature to normal; no relapse was seen if the patient took the full course and no toxic by-effects have been noticed.

Our intention mainly is to draw attention to the existence of kala-azar in this part of India which was supposed to be free from this infection and unlikely to be affected by it. Whether any of our cases could be considered as indigenous Jaipur infections has to be examined now (see table, col. 'residence'). No. 1 certainly acquired the infection in Calcutta, no. 2 most probably in Bihar and no. 8 in Gorakhpur district.

No. 9, positive for Leishman-Donovan bodies and the only female in our series, spent three years in Akbarpur, U.P., but, according to her history, remained healthy one full year after returning to Rajputana; the question is whether such a long incubation period is possible, whether

the girl, though intelligent, did not notice the beginning of her illness, or whether she was infected in Narnaul, a district of Patiala State, bordering on Jaipur.

Interesting is also no. 6 who showed Leishman-Donovan bodies in the sternal marrow and definitely denied having left Jaipur State for the last 7 years when he returned from a 6 months' stay in Calcutta where he suffered from fever. The movements of no. 7 who belongs to a nomadic tribe could not be traced. Nos. 3, 4 and 5, however, maintained that they spent all their life in Jaipur State. Unfortunately, these three cases are the least convincing of this series. Neither a positive sternal smear nor a clear-cut therapeutic response to specific treatment, nor even a really characteristic blood picture help us in raising the diagnosis above doubt. It is based solely on a positive Napier's aldehyde reaction, facilities for carrying out complement fixation tests (Grevall, Sen Gupta and Napier, 1939) having not been at our disposal.

We are unable, therefore, to make a definite statement whether kala-azar of undoubted Jaipur origin exists, being not sure whether a fully positive aldehyde test, not corroborated by the presence of Leishman-Donovan bodies in sternal smears; is sufficient for establishing this diagnosis.

Summary

Nine cases of kala-azar are reported. It is discussed whether available evidence permits to extend the limits of the kala-azar area as far west as Jaipur State.

THE ERYTHROCYTE SEDIMENTATION RATE IN RHEUMATIC FEVER AND OTHER CONDITIONS

By M. NARAYANA PAI, M.B., B.S.

Department of Bacteriology, Stanley Medical College, Madras

THE sedimentation rate of the red blood cells is considered by many to be a valuable aid in the prognosis of tuberculous affections, rheumatic infections and various other conditions although it has no value in the actual diagnosis of these conditions. Westergren (1921) considered the red cell sedimentation test to be of very great

value in prognosis, and Heaf, Grafe, Levinson and others have shown how the test is a gauge of cell destruction in lung disease.

The red blood corpuscles settle more rapidly in the blood of women than of men and very much more rapidly in pregnancy after the third or fourth month. Increased rate of sedimentation is seen in tuberculosis; in this disease it increases with the activity of the disease. In cancer the rate more or less closely parallels the degree of malignancy. In localized acute inflammations the rate appears to increase with the leucocyte count (Todd and Sandford, 1944).

The factors of prime importance in the rate of sedimentation of the red blood cells are the concentration of protein in the plasma and the number of the red cells (Fraser and Rennie, 1941). Fahracus (1925) showed that sedimentation of red blood cells occurred with great rapidity when there was an increase in the fibrinogen and globulin in the plasma and a fall in the albumin. It is well recognized that plasma fibrinogen and also globulin are increased by infectious processes and when tissue destruction is occurring, *i.e.* in just these conditions, in which the sedimentation rate is above normal (Fraser and Rennie, 1941). Increased rate of sedimentation of red blood cells occurs in anæmias. This is probably due, not to the red cells themselves, but due to the associated changes in the proteins in the plasma (Fraser and Rennie, 1941).

There are various methods of determining the erythrocyte sedimentation rate (E.S.R. for purposes of brevity). Westergren's method is both simple and for all practical purposes very useful. By this method, the normal rate for healthy men is 0 to 15 mm. in 1 hour and for healthy women 0 to 20 mm. in 1 hour (Todd and Sandford, 1944).

The normal limits (after 1 hour) according to textbooks are 3 to 5 mm. in the case of men and 4 to 7 mm. in the case of women, but in the experience of Napier and Das Gupta (1941) amongst Indians in Calcutta, the figures were 3 to 15 mm. in the case of men and 5 to 40 mm. in the case of women. Venkatrao (1940) states that in normal adult men in South India the E.S.R. ranges from 8 to 12 mm. and in women from 10 to 15 mm. but the rate is obtained by adding the reading of the first hour and half of the reading of the second hour and the result divided by two. The higher the figure the greater are the chances of active disease being present. There is no diagnostic significance about this test. When once a diagnosis is established and the test is repeated fortnightly, any increase in the rate means a rapid increase of the disease, increased cell destruction in the diseased lung for instance.

Similarly, in cases which are improving, the rate usually falls and returns to normal in arrested cases. Very often, impending pleural effusion or any exacerbation of disease can be foretold in these cases by the increase in the

sedimentation rate, days before the actual onset of the trouble.

This paper is based upon the observations of the author at the Government Stanley Hospital, Madras, and Stanley Medical College, Madras, from July 1940 to February 1945, on 47 normal healthy persons (36 men and 11 women) and 158 other cases. Out of the latter, 46 were cases of acute or sub-acute rheumatic fever, 16 of chronic rheumatic heart disease, and 96 of conditions such as myeloid leukaemia, fibroids, congenital heart disease, Banti's disease, tuberculous glands, etc.

Table I gives the E.S.R. in 36 normal males and 11 healthy females.

TABLE I

151A	22	Laboratory attendant.	5	11

Total 36 cases.

Average for healthy males—

$$1 \text{ hour} = \frac{162}{36} = 4.5 \text{ mm.}$$

$$2 \text{ hours} = \frac{383.5}{34} = 11.3 \text{ mm.}$$

TABLE I—concl'd.

Case number	Age	Occupation	E.S.R., MM.	
			1 hour	2 hours
NORMAL FEMALES				
8	20	Medical student	5	9
9	22	Do.	11	24
11	21	Do.	16	38
12	26	Do.	18	40
25	23	Do.	4.5	13
26	21	Do.	7	15
66	..	Nil	10	45
67	35	Doctor	15	48
115	18	Nil	10	15
119	20	Student	14	36
96	24	Nil	14	28

Total 11 cases.

Average for healthy females—

$$1 \text{ hour} = \frac{124.5}{11} = 11.3 \text{ mm.}$$

$$2 \text{ hours} = \frac{301}{11} = 27.4 \text{ mm.}$$

Thus the average E.S.R. for males ranges between 1 and 10 mm. (1 hour) with an average of 4.5 mm. and between 5 and 30 mm. (2 hours) with an average of 11.3 mm. In the case of

61 mm. to 166 mm. at the time of admission into hospital. In some cases the E.S.R. was repeated at intervals till the time of discharge (table II).

Sixteen cases of chronic rheumatic heart disease were also studied. Out of these, 6 were females and 10 were males. The E.S.R. in the case of males ranged from 2 mm. to 35 mm. at the end of 1 hour and from 3 mm. to 70 mm. at the end of 2 hours. In the case of females, the figures were 3 mm. to 32 mm. at the end of 1 hour and 6 mm. to 67 mm. at the end of 2 hours.

healthy females, the figures are between 4.5 mm. and 18 mm. (1 hour), average 11.3 mm., and 9 mm. and 45 mm. (2 hours), average 27.4 mm.

Of the 46 cases of acute and sub-acute rheumatic fever 19 were females and 27 males. The ages ranged from 6½ to 45 years. The E.S.R. at the end of 1 hour ranged from 37 mm. to 165 mm. and at the end of two hours from

The E.S.R. was also done in other conditions. The following interesting cases are mentioned :—

Case no. 1.—Chinnakolandai, Hindu, female, 15 years. Admitted on 30th July, 1940, for fever and painful joints. Diagnosis: Rheumatic fever. Cardiac signs also present.

E.S.R. on 9th August, 1940, was 95 mm. and 112 mm. (1 hour and 2 hours respectively).

Temperature reached normal on 22nd August, 1940, and remained so till her discharge from hospital on 17th September, 1940. Pulse rate had fallen to between 80 and 88 per minute from 22nd August, 1940, till date of discharge. E.S.R. on 11th September, 1940, however, was 60 and 96 mm. (1 hour and 2 hours respectively) though her temperature was normal. This suggests that the rheumatic infection had not completely subsided, though clinically the patient was all right.

Case no. 9.—Ananthanarayanan, Hindu, male, 24 years. Admitted on 21st September, 1940, for fever and painful swelling of joints. Cardiac signs such as presystolic murmur in mitral area, etc., were present. Temperature between 98° and 100.8°. Reached normal on 25th September, 1940. Pulse rate between 80 and 84 on and after 25th September, 1940. Diagnosis: Rheumatic fever.

E.S.R.

	1 hr.	2 hrs.
24-9-40 ..	144 mm.	..
15-10-40 ..	72 mm.	..

Remarks.—E.S.R. continues to be high, though temperature and pulse are normal.

Case no. 22.—Shanmugavalli, Hindu, female, 13 years. Admitted on 29th January, 1941. Diagnosis: Rheumatic fever.

E.S.R.

	1 hr.	2 hrs.
31-1-41 ..	115 mm.	140 mm.

Temperature and pulse rate normal from 1st February, 1941, onwards.

E.S.R.

	1 hr.	2 hrs.
18-2-41 ..	38 mm.	91 mm.
11-3-41 ..	19 mm.	48 mm.
25-3-41 ..	18 mm.	45 mm.

Remarks.—Though her temperature and pulse rate were normal from 1st February, 1941, her E.S.R. on 18th February, 1941, remained fairly high—38 mm. and 91 mm. (1 and 2 hours).

Case no. 24.—Loganayaki, Hindu, female, 31 years. Admitted on 25th January, 1941, for fever and pain over various joints. Had two similar attacks 10 years ago and two years ago. Diagnosis: Rheumatic fever. Temperature ranging between 100° and 105°.

E.S.R.

	1 hr.	2 hrs.
31-1-41 ..	134 mm.	137 mm.

Temperature reached normal on 1st February, 1941. Discharged against medical advice on 5th February, 1941. Re-admitted on 11th February, 1941, with fever and pain in joints.

E.S.R.

	1 hr.	2 hrs.
26-2-41 ..	66 mm.	110 mm.
11-3-41 ..	55 mm.	102 mm.

Remarks.—This patient went home against medical advice. She should have remained in hospital till her E.S.R. came down to within normal limits.

The above cases stress the importance of estimating the E.S.R. before the patient is discharged from hospital. When the temperature and pulse rate are normal, a high E.S.R. shows that the rheumatic process has not subsided completely, the cell destruction is going on and that the patient needs rest for some more time before he or she is permitted to resume work. In this respect, the blood sedimentation apparatus is as important as the clinical thermometer, stethoscope and blood pressure apparatus in the armamentarium of the practitioner. As the method is very simple, and can be performed at the bed-side, more frequent use of this procedure is recommended.

Summary and conclusions

1. The erythrocyte sedimentation rate has been determined in 47 normal persons, 36 males and 11 females, the majority of whom were medical students and members of the staff of the Stanley Medical College, Madras, and Government Stanley Hospital, Madras.

2. In the case of normal healthy males, the E.S.R. ranged from 1 to 10 mm. at the end of 1 hour with an average of 4.5 mm., and from 5 to 30 mm. at the end of 2 hours with an average of 11.3 mm.

3. In the case of healthy females, the E.S.R. ranged from 4.5 to 18 mm. at the end of 1 hour with an average of 11.3 mm., and from 9 mm. to 45 mm. at the end of 2 hours with an average of 27.4 mm.

4. The E.S.R. was also studied in 46 cases of acute and sub-acute rheumatic fever admitted into the Government Stanley Hospital, Madras, during the period July 1940 to February 1945, of whom 19 were females and 27 males. The rate was generally higher in the case of females and ranged from 37 mm. to 165 mm. at the end of 2 hours, depending upon the severity of the clinical symptoms.

5. In 16 cases of chronic rheumatic heart disease (6 females and 10 males), the E.S.R. in males ranged from 2 mm. to 35 mm. at the end of 1 hour, and from 3 mm. to 70 mm. at the end of 2 hours. In the case of females, the figures were 3 mm. to 32 mm. at the end of 1 hour, and 6 mm. to 67 mm. at the end of 2 hours.

6. The E.S.R. was studied in other conditions such as myeloid leukaemia, Banti's disease, chronic kala-azar, congenital heart disease, tuberculous glands of the neck, mediastinal tumour, etc.

7. Four cases of special interest are mentioned in which, though the temperature, pulse rate, etc., reached normal and the patient looked clinically all right, the E.S.R. remained high. A suggestion is made that in such cases, the patient

should be given rest in bed for some more time and fully investigated, until the E.S.R. reaches normal limits.

I am thankful to Dr. P. Kutumbiah, Principal, Stanley Medical College, Madras, and to Captain M. G. Kini, Superintendent, Government Stanley Hospital, Madras, and to the Physicians of the same hospital for the clinical notes of the cases and for facilities provided in this investigation. My thanks are also due to Dr. Miss D. D. Bunyan of the Department of Bacteriology, Stanley Medical College, Madras, for her valuable assistance in this investigation and to the medical students, house surgeons and house physicians of the Stanley Medical College, and Stanley

Hospital, and other volunteers for their hearty co-operation.

A Mirror of Hospital Practice

SODIUM THIOSULPHATE AS AN ANTIDOTE IN PENICILLIN EXFOLIATIVE DERMATITIS

By N. A. AIENGAR, L.R.C.P., M.R.C.S.
 K. S. NARAYANASAMY, M.B., B.S.

and

B. R. LAKSHMINARASIMHALU NAIDU, L.M.P.
McGann Hospital, Shimoga (Mysore State)

THIS complication is not very common. The army records have reported only one case in a record of 10,000 cases treated with penicillin and that in a person who had suffered from syphilis. The interesting feature of the case reported below is that this patient too had some previous history of syphilis which was elicited rather late and that she was cured of her distressing condition by treating her with injections of sodium thiosulphate which is used in exfoliative dermatitis due to arsenic. We had failed with all other measures, and this was tried as the last resort with very dramatic results. In our experience we found a fair number of cases getting some sort of dermatitis and distressing itching after treatment with penicillin.

Patient, a Hindu woman, aged about 22 years, admitted on 24th January, 1946, for septicæmic pneumonia.

The patient gave birth to twins about a month prior to the date of admission. She was well for a week after delivery and then developed continuous fever with rigors now and then. This continued for a fortnight and she was brought to the closest dispensary. There she developed cough and pain in the right side of the chest. Fever continued. Having found no relief she was brought to this hospital for further treatment.

24th January, 1946.—On admission the patient was found to be suffering from septicæmic pneumonia in the right base. The general condition of the patient was rather acute and

critical. As penicillin was not available immediately, she was put on sulphapyridine tablets two 4-hourly for three days and then two t.d.s. for four days. Her general condition was slightly better but the temperature had not touched normal.

On 7th February, 1946, penicillin injections were started—20,000 units per dose—at 3-hourly intervals. She had 9 injections in all totalling 180,000 units. Cough, pain in the right side of the chest and fever persisted. Sedatives with iodine of potassium were given as also calcium by mouth.

On 20th February, 1946, the patient developed extensive urticarial rash and diarrhœa. Two days later she developed stomatitis and ulcerative glossitis. Calcium injections and vitamin B complex, particularly nicotinic acid tablets, were given but with no appreciable improvement.

On 4th March, 1946, she developed extensive exfoliative dermatitis all over the body, the skin peeling off in flakes. There was also oozing of serous fluid in certain parts. Diarrhœa, cough and fever continued and her condition became very critical. Cod-liver oil application, calcium and vitamin B₁ injections were tried but were of no avail.

7th March, 1946.—As sodium thiosulphate is effective in arsenical dermatitis and as all other measures of alleviating the condition had proved a failure, this drug was thought of and started immediately. Ametoxyl sodium (M. & B. sodium thiosulphate) injections were given intravenously every day for five days. The patient showed dramatic signs of improvement from the second day onwards. Oedema subsided, exfoliations got less extensive. Diarrhœa was controlled and the temperature became intermittent.

12th March, 1946 to 16th April, 1946.—From 15th March, 1946, the temperature struck normal and remained there, showing a rapid progress. There was less cough and the skin became normal. Stomatitis and ulcerative glossitis disappeared

Appetite improved. The patient was put on 'Vitrated' Upjohn's and more liberal diet. By 16th April, 1946, she was able to walk about and was discharged cured.

A CASE OF RICHTER'S HERNIA STRANGULATED IN THE FIRST DESCENT IN A CONGENITAL RIGHT INGUINAL HERNIAL SAC

By M. MUKHERJI

Resident Surgeon, Campbell Hospital, Calcutta

S. C. S., a Hindu male, aged 25 years, cultivator, was brought to the Campbell Hospital on 23rd January, 1947, at 5 p.m., with severe (colicky?) pains all over the abdomen.

On 20th January, 1947, at about 12 midnight, the patient passed a stool. The stool was a constipated one and was followed in a few minutes by pain of colicky type around the umbilicus. The pain increased and ultimately spread all over the abdomen. At the same time he noticed a cord-like swelling near the right groin. He started vomiting a few hours later and vomited several times. Next morning he noticed that his scrotum was swollen on the right side. Since the onset of pain, the patient passed no flatus or faeces. Gradually the abdomen got distended and the swelling in the scrotum increased. He did not vomit during the few hours he was in the hospital before operation. Patient took fluid feeds throughout.

On examination.—Patient did not look very toxic or badly dehydrated. Tongue was slightly moist, pulse 100 per minute, BP 120/90, and temperature 98.4°F. Abdomen was moderately distended with prominent coils of intestine showing visible peristalsis. Liver dullness was present. Shifting dullness was not present. Auscultation proved increased peristalsis. In the region of internal abdominal ring and lateral half of the inguinal canal, slight fullness and a small tense swelling (1 inch \times $\frac{1}{2}$ inch) were felt. The spermatic cord below the swelling was felt to be thicker than that on the left side. The right side of the scrotum was distended with opaque fluid under low tension, the testis was found to be of normal size and not painful though the patient gave history of an old orchitis on the same side.

An enema was given with no result. Patient could not be sure whether he passed flatus or not.

A provisional diagnosis of intestinal obstruction due to a small bit of intestine being pinched in internal abdominal ring was made but the findings of the inguinal region were more like those of funiculitis.

Operation.—The right inguinal canal was opened under open ether anaesthesia. On opening the sac a small bit of intestine was found lightly congested on the lateral side and blood-stained fluid welled up from the scrotal side of

the sac. The intestine was relieved from the constricting band just below the neck of the sac. In order to examine the proximal portions of the intestine, about 3 inches of the loop were pulled out with difficulty. Obviously the mesentery was short and the portion of the gut that was strangulated was found to belong to the lowest part of the ileum. About three-fourths of the circumference was incarcerated. On exploring the sac on the scrotal side, it was found to be continuous with the tunica vaginalis which contained about 4 oz. of blood-stained fluid. The intestinal wall regained peristaltic movements after warm applications and was replaced into the abdominal cavity. The upper portion of the sac was excised at the neck and the lower half was everted on the testis as is done in hydrocele operations. The wall of the inguinal canal was not repaired. Patient made an uneventful recovery.

Discussion.—In 1778 Richter described a small rupture in which only a portion of the gut wall was incarcerated and recognized this as a distinct type of strangulation in a hernia. There were 94 references in literature when Fowler's paper describing two cases was published in 1899. Between 1899 and 1928 there are references to 45 cases. And after 1928 there are 15 references more. Most of these references described Richter's hernia occurring in the femoral canal. Very few cases are recorded in the inguinal canal. Muntabhorn of Guildford mentioned 3 cases in Guy's Hospital reports, 1944, of which one was femoral, one obturator and one inguinal. He said that though the symptoms were like those of ordinary strangulation, the distension was not marked and constipation might not be absolute. A few cases in the inguinal region did show absolute constipation. The interesting and important points in my case are:—

(a) The patient was a manual labourer of 25 years of age, with a congenital hernial sac.

(b) He developed a strangulated hernia of Richter's type in the first descent due to straining, at stool, and a secondary hydrocele from the collection of fluid from the congested gut wall.

(c) Though he had intestinal obstruction for 65 hours, he did not look very ill nor had he marked distension. The absolute constipation may be supposed to be due to the kink in the intestinal loop. The reason for his getting a Richter's hernia might be the shortness of the mesentery and the strong inguinal sphincter present.

A strong inguinal sphincter is really the important barrier in preventing a hernial protrusion.

I thank Major E. H. Lossing, Superintendent, Campbell Medical School and Hospital, and Dr. S. K. Chatterjee, Honorary Surgeon, Campbell Hospital, for their permission to publish this case, and Drs. S. Banerjee and S. Ray for their assistance.

150 years old...

1947 marks the 150th anniversary of Howards of Ilford, manufacturers of fine chemicals. Latterly, as most of our friends know, supplies have not been so freely available as they, or we would have wished, although conditions are improving. We would like to assure our friends, that we are doing our utmost to let our agents have everything we can spare, and that they, in turn, try to make the fairest possible distribution of what they get.

HOWARDS OF ILFORD

VIROL

and the proper nutrition of children

For more than forty years doctors have been observing what happens to children when they are given Virol in addition to their ordinary meals. In Hospitals, Welfare Centres and in private practice they have seen over and over again how quickly the growing body responds to Virol and how lasting is the improvement in growth, health and energy.

Virol is a concentrated and very

palatable food prepared from Malt Extract, specially refined Animal Fats, Eggs, Sugars (including Glucose), and Orange Juice, with added Mineral Salts and Vitamins. Virol is designed to provide, in carefully balanced proportions, those essential food factors (not vitamins alone, but also many other just as important, including iron, calcium, phosphates, etc.) which are most likely to be deficient in the rest of the diet.

Agents for India:

Messrs. A. H. Wheeler & Co., Asian Building, Nicol Road, Ballard Estate, Bombay

Virol Ltd., London, England.

LIVOGEN

TRADE MARK

The Rational Tonic

Livogen has become firmly established as a general tonic the effects of which are marked and lasting. Its effects are produced by replacement of essential substances in the tissues and not by a shortlived stimulation of tired and depleted tissues.

Livogen provides vitamins of the B group, the active groups in the enzymes catalysing the oxidation-reduction metabolism of carbohydrates, proteins and fats. In addition it provides liver extract, the hæmopoietic activity of which is well known. Thus Livogen provides for efficient oxidation (dehydrogenation) in the body metabolism and promotes the provision of adequate oxygen, required in these processes, by correcting subclinical anæmic states.

Livogen may therefore be given to convalescents and to malnourished or otherwise debilitated patients to whom the physician would hesitate to give tonics which stimulate but do not provide the necessary factors for the maintenance of metabolism at the higher level.

Stocks of Livogen are held by leading chemists and full particulars are obtainable from—

JUNE

PRIMARY ATYPICAL PNEUMONIA

THE failure of sulpha drugs to cure cases of pneumonia, sporadic or in certain outbreaks, brought to light two facts: (1) Certain cases do not conform bacteriologically to the accepted picture of pneumococcal pneumonia, even when other known causes are excluded. (2) Certain cases do not conform clinically to the accepted picture of either lobar pneumonia or broncho-pneumonia. X-rays may show a mild, moderate or marked infiltration in one or several lobes of the lungs. The temperature may be slight or as high as 105°F. The disease may run its course in a few days or may last several weeks. These and similar points have been discussed in this journal previously (Editorial, 1944).

Later, the failure of penicillin and streptomycin focused more attention on the subject and brought to light four other facts: (1) It is now believed that in America the disease is much more prevalent than lobar pneumonia in the adult population, civil or military (Hyman, 1947). Mild cases do not attract attention and are accepted as cases of bad cold on the chest. (2) The disease is associated with the development or increase of the cold iso(haemagglutinin)s in the blood of the patient. These isonins agglutinate the red blood corpuscles of the same group, of the subject's own blood—autohaemagglutination—or of a subject belonging to group O, at a low temperature—about 4°C. (3) The disease is caused by a virus, probably allied to that of psittacosis, and has been recently transmitted to human volunteers inoculated intranasally with pooled sputum, nasal washings and bacteria-free filtrates. (4) The patient's serum gives a false-positive Wassermann reaction.

The detection of the cold isonins has been used as a means of diagnosis (Turner, Nisewitz, Jackson and Berney, 1943; Shane and Passmore, 1943; Dyke, 1947; Hyman, *loc. cit.*). The technique is simple. The serum is diluted serially, 1 in 4, 1 in 8, 1 in 16. . . . The dilutions are mixed with equal volumes of a 1 per cent suspension of the test corpuscles and the mixture left overnight in a refrigerator (about 4°C.). Next day the deposit in the tubes is examined quickly while the tubes are still cold. The examination is best done by holding the tube on the sub-stage concave mirror of a microscope (lying on its side). The edge of the deposit of the red blood corpuscles which have simply been deposited by sedimentation is smooth and puts out a tongue on tilting the tube. The edge of the deposit of the red blood corpuscles which

have been agglutinated is crinkly, granular, rough or firm and does not put out a tongue on tilting the tube. The haemagglutination is abolished by leaving the tubes in a water bath at 37°C. or in an incubator at the same temperature. A macroscopic examination is enough. A titre of 1 in 32 is considered diagnostic. The titre is indicated by the *initial* dilution of the serum, not the *ultimate* dilution. (Hyman considers a titre of 1 in 50 diagnostic, with a slightly different technique.) Occasionally the titre reaches the high level of 1 in 20,000. The reaction, however, is not specific and is known to occur in malaria, mumps, orchitis and haemolytic anaemia (Hyman, *loc. cit.*).

The false-positive Wassermann reaction is an annoying discovery and adds one more condition to the long list of non-specific conditions responsible for a positive Wassermann reaction (Greval, 1943, 1946). A positive Wassermann in a febrile case showing chest symptoms calls for a concurrent test of the isonin content of the serum. Further, the high incidence of syphilis in America, as judged by the positive Wassermann rate, presumably needs a re-assessment, in view of the incidence of the atypical pneumonia in that country. Is it really 10 per cent? Do 'ten million Americans have it' really (Becker, 1937)?

Although the atypical pneumonia is not a serious disease the complications, probably caused by secondary infections, may be serious. They are bronchiectasis, necrotizing pneumonia, pulmonary abscess, pleural effusion, pneumothorax or empyema. The sulpha drugs and penicillin are, therefore, useful not only in therapeutic tests but also, later in prophylaxis against the secondary infections. They should be used as long as the high temperature persists. Otherwise symptomatic treatment suffices. The nourishment should be maintained.

Is the atypical pneumonia a newly born disease? Probably it is or has come round again in a cycle after a long absence. Otherwise the clinicians would not have been so emphatic in banning the diagnosis of primary broncho-pneumonia in the adult about thirty years ago. The disease clinically is suggestive more of broncho-pneumonia than of lobar pneumonia and is definitely primary. It could not have been missed if it had existed at the beginning of the century.

THE TWIN DOMINIONS AND THE INDIAN MEDICAL GAZETTE

By the time these lines appear in print the Indian Empire will have passed away handing over its assets and liabilities to the twin dominions of India and Pakistan. The *Indian Medical Gazette*, however, will keep its service unimpaired and its attention undivided for both the components of the old country which it has served for the last 81 years.

The first number of this publication appeared in 1860, eighty years after Victoria the Great, the Queen of England, had taken into her own hands the reins of the Government of India as the Empress of India, after terminating the merchant rule of the East India Company.

The journal is the oldest medical monthly of the Eastern hemisphere and will, of course, devote itself to medical problems, anxieties, interests and progress in India and in Pakistan alike. Medicine includes Public Health.

The journal has been run for the major part of its life by the officers of the I.M.S. That service too will have passed away. The journal, however, will carry on. From the ashes of the old phoenix will arise the young phoenix capable of lustier songs embodying Asian themes and more acceptable to the Asian ear.

The journal has a policy but no particular platform. Any structure with sound planks will do. From it will be delivered messages of health, happiness and strength: items which fall well within the province of medical men and enable a nation to unfold and develop all its potentialities, material and spiritual, and to win its neighbours' respect and gratitude.

Due to the prolonged disturbed conditions in Calcutta this number of the *Indian Medical Gazette* although dated June is appearing after 15th August, 1947, the date of the transfer of power to the twin dominions of India.

A SPECIALLY ESTEEMED CONTRIBUTOR

SUCH is Sir Leonard Rogers, K.C.S.I., M.D., F.R.C.P., F.R.S., I.M.S. (retd.), who has favoured us with an article entitled 'The Present Position of Antimony Treatment of Filariasis' on this page.

Sir Leonard retired under the age rule in 1920 to work in a wider sphere. This great loss to India, therefore, was a gain to every medical research worker all over the world.

Sir Leonard speaks on many subjects with such authority as is derived from a life-long study of facts, events and the inter-related causes and effects.

The younger readers in India who possibly limit their study of current literature to this journal only may not have read many articles by Sir Leonard before. The last article entitled 'Tetanus Neonatorum in the Tropics: A Suggestion for its Reduction' was published in these pages in July 1944, page 297.

Special Articles

THE PRESENT POSITION OF ANTIMONY TREATMENT OF FILARIASIS: WITH A SUGGESTION FOR ITS INTENSIVE USE

By SIR LEONARD ROGERS, K.C.S.I., M.D., F.R.C.P., F.R.S., I.M.S. (Retd.)

AMERICAN workers at Porto Rico have recently confirmed my investigations of 1919-20, which demonstrated that large intravenous doses of the trivalent sodium antimonyl tartrate have a lethal action on *Filaria (Wuchereria) bancrofti*. They have also made an important practical advance by extending this observation to the less toxic pentavalent antimony salts, which were not available at the time of my work on the subject. A brief review of present position of the subject will therefore be timely.

The discovery by J. B. Christopherson in the Sudan of the curative action of tartar emetic against infections with schistosome worms led me to try antimony salts in filariasis. In April 1919, I carried out preliminary trials at Puri with

the kind help of the civil surgeon, Dr. P. N. Das. Counts of the microfilaria in 20 cm. of evening blood were made daily before and after treatment with daily doses of a 2 per cent solution of sodium antimonyl tartrate, which I had found by animal experiments to be slightly less toxic than the potassium salt, tartar emetic. A preliminary note showed that 7 to 11 daily 5 c.c. doses in four cases, showing up to 100 microfilaria in 20 cm. blood before treatment, greatly decreased the number in all, and in one 11 doses reduced the number within 15 days to only 6 per cent of the former number.

This partial success led me to work at the Cuttack jail to allow cases to be kept under regular observation for much longer periods than proved to be possible at the Puri hospital. Microfilaria counts were made in 100 apparently healthy long-term prisoners, and 8 with an average count of 73 microfilaria per 20 cm. 9 p.m. blood were selected for treatment with daily doses of the sodium salt rapidly pushed up to 5 c.c. of a 2 per cent solution intravenously.

The immediate effect was striking, for at the end of six days the average number of embryos had fallen to only 10 per cent of the original number in the eight cases. Toxic symptoms led to the 5 c.c. doses being given only every other day up to 45th day, with an average total of 1.8 grammes of the sodium salt. Counts were made every day for 18 days, and then every three to seven days up to five and a half months; that is up to four months after cessation of treatment. Counts were also made in five control cases and the microfilaria were found to vary between 45 and 160 per cent of the original numbers. Immediately on reducing the frequency of the doses the average count rose to 45 per cent. Subsequently the cases resolved themselves into two groups of four each, the variations in the number of microfilaria in each of which is shown in a chart in my paper of 1920. The average counts of the four cases which relapsed are shown in the upper curve of continued lines with sharp peaks up to about the original numbers, which recurred every month after treatment was stopped, as did more frequent similar peaks in the control cases. On the other hand, the average numbers in the other four cases, shown by a broken line, fell steadily during the last three months without treatment to reach only 3 to 9 per cent of the original number. In these the antimony had a lasting effect.

However, the most important observation I made, as a result of frequent microfilaria counts in the evening blood over nearly six months, was that the regularly recurring peak rises in the control and in the relapsed cases were due to sudden appearance in the peripheral blood of very large numbers of thin young embryos, easily distinguished from older forms. This interesting finding was confirmed in 1922 by Roy and Bose at Puri, who also noted that these thin forms showed less developed cells than do the older forms. This confirms my view that these sudden increases are due to the birth of large numbers of young embryos at regular intervals in individual cases, just as Waring in 1882 showed that the intervals between attacks of filarial febrile lymphangitis remains the same over long periods in individual cases, although their frequency varies in different cases. My further observation that such young forms did not appear in the blood during the three months of steady decline in the numbers of microfilaria after cessation of treatment in the four recovering cases, led me to conclude that the adult worms had either been killed or very seriously damaged in these cases by the antimony treatment.

Explanation of the periodicity of filarial febrile lymphangitis.—Long ago Patrick Manson suggested the ingenious hypothesis that filarial lymphangitis is caused by the adult filaria periodically giving birth to unhatched ova instead of thinner free embryos. As early as 1904, I attempted to verify this hypothesis by search-

ing for ova in centrifuged material from a number of recently removed scrotal elephantoid tumours, but with completely negative results. The above observation would appear to explain satisfactorily the periodical attacks of lymphangitis by the sudden birth of such large numbers of young embryos causing additional lymphostasis in areas where lymphatic obstruction prevents their entry into the peripheral blood. Successful antimony treatment should in this case reduce the frequency of attacks of filarial fever and thus check the progress of elephantiasis. The following confirmation of my work shows that this is the case with patients who can stand the necessary large doses of toxic trivalent antimony salts.

Confirmation of the value of antimony in filariasis.—Firstly, a number of cases recorded by P. N. Das in 1920, Day in Egypt in 1921 and by Roy and Bose, working at Puri, in 1922, demonstrated that the large total dosage of sodium antimonyl tartrate I employed is effective in completely eliminating originally large numbers of microfilaria from the peripheral blood presumably due to the adult worms being killed. Secondly, cases were soon reported by myself and by P. N. Das in 1920, by Roy and Bose in 1922 and by Bär in the Dutch East Indies, in which periodical attacks of febrile lymphangitis were stopped, in the majority for long periods, by the same treatment. Thirdly, in 1922 Roy and Bose reported on treatment of fifty cases of elephantiasis of limbs, with careful measurements before and after. They obtained improvement in every case, commencing after five injections of 2 to 5 c.c. of 2 per cent solution of the sodium antimonyl tartrate, and reaching a maximum in some cases of two inches' diminution in the circumference of the limb. On the other hand in 1924 the British Guiana Filariasis Commission under Liper reported that tartar emetic was the best of many drugs they tested, but was of limited value. The toxicity of the full doses required has much limited the use of trivalent antimony salts in filariasis.

Trials of less toxic pentavalent antimony salts.—My Calcutta investigation was cut short by my leaving India early in 1920, preparatory to retirement under the age rules, before the less toxic pentavalent antimony salts, which proved much more effective than the trivalent ones in kala-azar, had become available. However, in 1929 R. N. Chopra and S. Sunder Rao reported on trials of a number of such antimony preparations at the Calcutta School of Tropical Medicine. Unfortunately the duration of the treatment, the total dosage used and the follow-up period were all insufficient to furnish anything but negative results. For example, only two cases were treated for 8 to 18 days with 0.1 to 0.3 gm.

Recent American Researches.—In 1945, Professor Culbertson of New York showed that the adult stage of a filarial worm, which inhabits

the pleural cavities of cotton rats, can readily be killed by antimony treatment; but that many months elapsed before its microfilarial stage completely disappears from the peripheral blood. With the help of six colleagues three years' investigation of the action of various antimony preparations on infections with *Filaria baneroffi* were carried out at the Porto Rico Medical School, and summarized in a recent paper read before the Royal Society of Tropical Medicine and Hygiene in London. The trivalent tartar emetic was used in four cases with an average total dosage of only 0.79 gm. in the course of 14 days: one-half the dosage spread over one-third of the time of those in my cases. Nevertheless, the number of microfilaria were ultimately reduced from 41 to 6 per cent of the original numbers. The best results were obtained in three series of cases treated with the pentavalent neostibosan, which was the least toxic. In the first series of twenty cases a total dosage of from 5.8 to 10.5 gm. was given in the course of 9 to 54 days and blood counts, recorded at six-monthly intervals up to two years, showed complete disappearance of the embryos from the blood at the end of from 25 days to 24 months in 16. Except in the case receiving only 9 gm., large decreases occurred in three more. In a second series two courses of the drug were given with an average total of 10.4 gm., with elimination of the embryo form from the blood after 5 to 14 months from the completion of the treatment in seven cases and great reduction in the other three. In a third series of five cases one intensive course of 9.5 to 15.5 gm., and an average of 11.8 gm., proved completely effective in three cases after one-half to 9 months, and produced great diminution of the microfilariae in the other two at the end of 16 months. Neostibosan is therefore the drug of choice in the treatment of filariasis, wherever the cost of such large doses of an expensive drug does not limit its use in view of the immense number of cases requiring treatment in such hyperendemic areas as Orissa.

Intensive tartar emetic treatment of helminthic diseases.—In this connection it is worthy of note that Alves and Blair (1946) have recently reported that 100 cases of schistosomiasis have been cleared of ova in the urine by the following two-day intensive course of tartar emetic. They injected intravenously on each of two successive days 1 to 2 grain doses in 10 c.c. of 5 per cent glucose, at a very slow rate by taking five minutes over each injection, three daily at three-hourly intervals. The total dosage was 7 to 14 grains, or about one grain for each 12 lb. body weight.

In view of the reduction in my eight cases of the microfilaria to only 10 per cent of the original numbers after only six daily large doses of sodium antimonyl tartrate, an intensive course of this drug appears to be worthy of a new trial in filariasis. As longer treatment with larger

total dosage will be required than in schistosomiasis, I would advise only two daily doses, one in the morning and the other in the evening. The patients should be in hospital and toxic symptoms watched for. Slight nausea is sure to occur, but actual sickness should be regarded as an indication for temporary cessation of the injections for a day or two. To make counts of microfilaria before and after treatment the measured amount of evening blood should be allowed to dry in thick films to ensure the film adhering firmly to the slide. Then place overnight in a very dilute solution of methylene blue in a basin or other suitable vessel to dissolve out the hæmoglobin and stain the microfilaria. The number in each slide can then be counted quickly with a low magnification and a movable stage.

SMALL, FAINT AND HIDDEN BLOODSTAINS

By S. D. S. GREVAL

LIEUTENANT-COLONEL, I.M.S.

(From the Imperial Serologist's Laboratory, School of Tropical Medicine, Calcutta)

NEED FOR CRITICAL VISUAL INSPECTION

This group needs a critical visual inspection and is composed of (I) stains caused by sprays and splashes, (II) smears, (III) traces left after wiping or washing, (IV) specks from the activity or squashing of vermin, and (V) hidden collections under nails of fingers and toes and in crevices and joints of weapons. All of them are represented in 14,200 (in 1940-41) to 18,500 (in 1939-40) stains tested annually from all over India for medicolegal purposes in this laboratory.

I. SPRAYS AND SPLASHES

Droplets from sprays and splashes falling on an object obliquely are in shape like old-fashioned soda-water bottles (with spheroidal bottoms, not made to stand), the first impact producing the bottom and the movement the neck. Only when they fall at right angles to the surface are they round. While several such round spots, in a pattern, will indicate a splash a single spot will fail to supply a clue: a

blood-sucking insect during a feed (*vide infra*) can deposit a similar spot.

II. SMEARS

The deposit of blood in a smear is superficial. While chemical and spectroscopical tests, proving the presence of blood, may be undoubted the serological tests, proving the presence of human blood, may be weak and the stain is, therefore, reported 'disintegrated'.

In reporting on human blood the term 'disintegrated' denotes, conveniently, all failures to find human blood after blood has been found, including weak reactions which in experimental work may be accepted as positive but must be rejected for medicolegal purposes. The same remarks apply to the determination of the source of animal blood.

Incidentally, the stability of the reaction of the shed blood in India is not of the same high order as that described by workers in colder climates. The serum protein (i) turns insoluble, as a result of exposure to heat (and possibly light) and (ii) decomposes, as a result of putrefaction, much more frequently than in Europe.

III. TRACES LEFT ON FABRIC AFTER WIPING A WEAPON ON IT OR AFTER WASHING IT

Streaks are likely to be seen with a hand lens in such stains. One important feature of a washed stain is that the edge may be stiffer than the centre and give a better serological reaction. This is due to the accumulation of serum along the edge when a clot has formed and contracted on the fabric prior to washing which aims at removing the clot only. The chemical and spectroscopic tests may be strong in the centre, if a minute fragment of the clot has been left, and weak or absent along the edge. A specimen, however, must be positive spectroscopically before it is tested serologically. This condition must be rigidly adhered to until the chemical luminescence test for blood (McGrath, 1942; Naidu and Pitchandi, 1943) has been tried extensively and found to be superior to the spectroscopic test. Spectroscopically negative and serologically positive stains are occasionally found among washed stains: the report on them is 'No blood found'.

IV. SPOTS FROM THE ACTIVITY OR SQUASHING OF VERMIN

Insects are known to pass droplets of unaltered blood from the anus just after commencing a feed. The droplets so passed and deposited are small but recognizable as such by the unaided eye.

The stains resulting from the squashing of engorged vermin (including insects, ticks and even leeches) are sharply angular in outline. Recognizable bits of the vermin may be present (scales and bits of eyes from mosquitoes; eggs, bristles and cuticle from bed bugs; tracheæ

from both; for instance). The body pulp of the vermin does not soak into the fabric like blood. Even in the absence of the body pulp and bits it is quite easy to say whether a droplet of blood has dropped on the fabric as a free globule or has been squirted out of another small object under pressure (angular outline), with reasonable certainty.

Mosquitoes and bed bugs may suck blood from a person of one blood group and on being squashed on articles of another person of another blood group may create a false evidence against the latter of being in possession of someone else's blood. The writer has fed newly hatched mosquitoes and bed bugs on blood of group O, A, B and AB and demonstrated the groups in stains produced by squashing the insects on chemically pure filter paper (Greval, Bhattacharji and Das, 1944). The mosquitoes were squashed 3 hours and 24 hours after the feed. The bed bugs (which were fed for several days) were squashed 3 hours after the last meal (24 hours' experiment was not undertaken). A fully engorged mosquito and bed bug can provide enough material for an absorption test.

Professional keepers of leeches empty them, after application and engorgement, by pricking near the posterior extremity and then milking. The blood of a certain group may drop accidentally and even be squirted intentionally on articles of a person of another group and again create a false evidence. Outlines of such drops are not angular.

Even lice crushed between thumb nails (the usual method of destruction) may leave the blood of a different group under the nails of a subject. The nails will certainly be found to be stained with human blood.

V. HIDDEN COLLECTIONS UNDER NAILS OF FINGERS AND TOES AND IN CREVICES AND JOINTS OF WEAPONS

When blood is found on the nails of fingers and toes certain exclusions become necessary. (i) In the case of the fingers the person (a) must not be suffering from skin conditions inducing scratching and drawing blood and (b) must not have killed lice (*vide supra*). (ii) In the case of both fingers and toes the nails should be cut with care and local bleeding avoided. The Indian barber is also a manicurist and chiropodist. He does not cut nails with clippers but pares them with a special instrument in one movement. He is quite likely to cut the nail-bed and cause capillary bleeding at times, especially in his zeal to remove as much of the nail as possible.

For excluding the possibility of traces of blood the suspected weapons are usually dis-jointed and the newly exposed surfaces tested. It is possible to remove enough material for examination by washing out the joint with normal saline contained in a teat pipette. A

previous soaking (wrapping in chemically pure filter paper soaked in normal saline and leaving in an ice chest overnight) may be necessary. This process should be tried, at least in the case of expensive and artistically valuable weapons, before destruction is resorted to. The same remarks apply to expensive clothing and important documents (including those carrying signature in blood; at least one such exhibit has been tested during the last thirteen years). A method for expensive fabrics has been described previously in connection with determination of blood groups from stains (Greval, Bhattacharji and Das, 1943).

AN OPINION OF THE SIZE, QUALITY AND CAUSATION OF THE STAINS

The value of such an opinion is obvious. A smear of blood where a pool is expected, small spots which though positive for human blood may be caused by insects, traces of blood under the finger nails of a sufferer from bad itch, a splash on a protected part of a garment or from a direction not consistent with the rest of the evidence, are all significant and in favour of the defence.

An error emerging from the following sequence of events is possible: (1) A Chemical Examiner receives a garment bearing many stains suspected to be bloodstains by the police and specially marked for examination. (2) He cuts out small fragments from all marked areas, examines them and finds them negative for blood. (3) He also notices an unmarked minute spot (possibly of insect origin) and finds it positive for blood. (4) He forwards only the minute positive spot to the Imperial Serologist who finds the blood to be human. (5) The positive report of the Imperial Serologist and the garment with many stains and holes in it are placed before the Court. (6) The Court forms an opinion that all areas examined (corresponding to the holes) are stains of human blood (from a personal communication from Rai Bahadur K. N. Bagchi, Chemical Examiner, Bengal, 1943). As is well known, Chemical Examiners (and the Imperial Serologist who is also a Chemical Examiner) are exempt from appearing in Courts under Section 510 of the Criminal Procedure Code. Their written report, therefore, should be more descriptive.

Faint stains are bound to be 'disintegrated' mostly. Their proportion varies from province to province in India depending upon the methods employed in investigation [Annual Reports of the Department of Imperial Serologist and Chemical Examiner to the Government of India; last published report (Greval, 1940)].

These remarks apply to stains collected for determining the source of animal blood also.

SUMMARY

1. Small, faint and hidden stains are discussed. Even though positive for human blood

they may not be associated with criminal violence.

2. The value of a relevant description of a stain, including causation, is pointed out.

Medical News

FUTURE OF COTTAGE HOSPITALS

By A. W. HASLETT

(Abstracted from Release No. F425, dated 14-3-47 offered by the United Kingdom Publicity Services, New Delhi.)

THE name 'cottage hospital' calls up a picture of roses and old England which bears little relation either to its past history or present appearance. Tradition indeed suggests that the name may have originated in the presumed custom, in some villages, of setting aside a cottage which could be used by doctors in their work. A more prosaic, but more probable, explanation is to be found in the fact that the word 'cottage' was once used to cover 'a small country residence', as well as the traditional village cottage with its roses round the door, and character-lined occupants which were at one time so popular with film producers.

The first cottage hospital was instituted in 1859 at Cranleigh, a Surrey village, by Alfred Napper, Fellow of Britain's Royal College of Surgeons. The house which he converted for the purpose was rather a small country house than a cottage in the ordinary sense. Before that date, all cases of accident and illness in villages and country districts had to be treated either at the county hospital—if they could survive a coach journey of perhaps two or three hours on indifferent roads—or else in their own homes.

For the first five years, progress was slow. Cottage hospitals were opened, on the average, at the rate of two a year. But in 1866 no fewer than 14 cottage hospitals came into being, and by 1870 the annual increase had reached 17. By that time, antiseptic surgery was beginning to win recognition, and by 1880 the need for aseptic conditions had provided an overwhelming case for operation under conditions of assured cleanliness in hospitals.

The first cottage hospitals were essentially places for the treatment of the sick poor. Of the first 100 patients at the Cranleigh Hospital, 67 were parish paupers, 7 more were incapable of paying the surgeon, 16 were 'in humble circumstances', and for the remaining 10 cases fees were paid by the poor law guardians.

As time went on, the status of cottage hospitals was steadily raised. Whereas, at the time of their first foundation the rich were treated at home, they soon realized the advantages of hospital treatment and the local cottage hospitals began to be used by all classes in country districts, for emergencies and minor operations.

To-day, the main characteristic of a cottage hospital is that it is a hospital staffed by local doctors, none of whom normally would claim to be surgical specialists, although a number in any area have more

or less regular experience of surgery within limited fields. The dictionary definition is that it is a hospital with no resident doctor. Hospital statistics are on the basis of size. In England, outside of London, there are some 120 hospitals with less than 30 beds, most of which would be classed as 'cottage hospitals', and there are another 14 in Scotland.

As to the fate of these 120 smaller hospitals under the unified hospitals service, which will be introduced under the National Health Service Act, it is too early as yet to make detailed forecasts.

Under any organization, however, it is a safe assumption that the majority will continue to serve a useful purpose. There is a clear advantage to the patient in remaining within easy reach of his friends. Besides, most of these hospitals have been paid for out of local subscriptions and there would be natural opposition to their disappearance.

There is also a genuine need for accommodation in which general practitioners can treat those of their patients who are not ill enough to need the services of a major hospital, but who cannot be satisfactorily looked after in their own homes.

The greatest difficulty which may be experienced, under State responsibility, is in defining the limits to which general practitioner surgery should be allowed to go—if, indeed, there should be general practitioner surgery at all. In favour of the country surgeon—who is seldom wholly a surgeon, but rather does the surgical work of his district—it may be argued that he is perfectly competent to remove the tonsils and adenoids of his child patients, and that the occasional surgical emergency really does arise in which a few hours of time gained is worth more to the patient than any specialist experience.

The most likely result would be that most of Britain's present cottage hospitals will continue very much as before, but with a tendency for an increasing proportion of operations to be transferred to major hospitals, as transport and organization improve.

HIGHER-POTENCY PENICILLIN

(Abstracted from the *Pharmaceutical Journal*, 23rd November, 1946, p. 331)

A HIGHER-POTENCY penicillin which is claimed to retain its active properties for three years without necessity of refrigeration, has been announced by the Heyden Chemical Corporation of America.

In a white crystalline form, the penicillin is said to possess a potency of 1,667 units per milligram.

DRUGS ACT, 1940

(Abstracted from *Science and Culture*, Vol. 12, No. 7, January 1947, p. 338)

REALIZING the serious situation arising out of the indiscriminate adulteration of drugs and chemicals in India, the Government of India appointed a 'Drugs Enquiry Committee' in 1930-31 with Lieut.-Colonel Sir Ram Nath Chopra as its Chairman. This Committee recommended:

(1) A drugs and pharmacy legislation on the lines of those existing in Great Britain and America.

(2) The establishment of a standardization laboratory to test and analyse the products and give authoritative opinion on the quality and potency of the drugs manufactured, imported and distributed for sale in India.

Pursuant to the above recommendations, 'The Drugs Act, 1940' (Act No. 23 of 1940) received the assent of the Governor-General on the 10th April, 1940. The implementation of the act, however, could not be given effect to owing to the war. The Government of India have now published a set of detailed rules under the Drugs Act, 1940 (see *Gazette of India*, dated 22nd December, 1945) and it is contemplated to enforce these rules from 2nd February, 1947.

This would involve the setting up of Central and Provincial Standardization Laboratories and an inspectorate charged with the duties of invigilation of drug manufacturing and distributing centres that would ensure the quality and potency of the medicaments.

MEDICAL FACILITIES FOR INDIANS IN EAST AFRICA

THE opening of the Pandya Memorial Clinic in Mombasa furnishes an example of self-help by Indians abroad.

There has been great need of hospital facilities for Indians in East Africa and this institution, it is hoped, will fill a useful rôle by providing medical and surgical facilities for Indians. It will also be a training centre for Indian nurses.

The institution, which has been established in memory of the late Mr. J. B. Pandya, will be run and staffed by Indians and will be equipped on modern up-to-date lines. Provision has been made for fifty beds to start with, and when fully equipped, the Clinic is expected to meet all the needs of the Indians in different branches of medicine.

INDIAN ASSOCIATION FOR THE STUDY OF HISTORY OF MEDICINE

(Abstracted from *Current Science*, Vol. 16, February 1947, p. 49)

At a meeting of the members of the staff of the Madras Medical and the Stanley Medical Colleges, held on the 5th February, 1947, the above Association was inaugurated.

'GRAFTING' IS A MAGIC WORD

ACHIEVEMENTS OF PLASTIC SURGERY

By GEORGE BILAINKIN

MODERN plastic surgery is a miraculous art by which sufferers from appalling injuries, unsightly wounds and deformities are enabled to face the world with new confidence. 'Grafting' is the magic word, and Nature, too, is generous, helping with the provision of skin, bone or cartilage in quantity, where it can be spared, on damaged or unexposed portions of the body.

Modern achievements include the correction of protruding ears in children and adults, nasal deformities, cauliflower ears, removal of tumours of eyelids, reconstruction of cleft lip and noses that have been shot away or burnt off.

One of the outstanding successes of plastic surgical treatment is the early covering of raw surfaces with skin in the form of grafts. This prevents contracture, deformity and disability and at the same time reduces stays in hospital and long periods of painful dressings. Another is the improvements in the technique of palate repair by which bad—and often unintelligible—speech results are avoided.

Replacing missing tissues

It is the aim of all plastic surgeons to replace missing tissues as soon as practicable by similar material from sources where it can be spared with impunity—skin by skin, cartilage by cartilage, or bone by bone.

Precisely four centuries ago, plastic surgery enjoyed its first period of popularity, thanks to Gaspar Tagliacozzi, of Bologna University, Italy, although it is known that the art existed at least a century previously. In World War I, restorative surgery progressed, for 26 million became casualties.

Sir Harold Gillies, of the United Kingdom, and Mr. Wilray Blair, of the United States, led with experiments, assisted by Mr. Tom Pomfret Kilner, a young Englishman from Blackburn. He had qualified in 1912,

but war gave him new opportunities and, by 1939, he had been responsible for thousands of astonishing cases in the many hospitals to which he was attached, in Harley Street, and also at Roehampton, where he was head of the Ministry of Pensions Department.

Churchill Hospital

To-day, as holder of the only Chair of Plastic Surgery in Britain, the Nuffield Professor at Oxford University, Mr. Kilner is hopeful about the development of the Churchill Hospital in the University City. This was first used by the American Hospital in Britain before America entered World War II. It was taken over by the U.S. Army, and later used as a head injuries hospital. Then it was handed to Oxford City, and is now an annexe of Radcliffe Infirmary. As it becomes possible to staff them, the wards are being opened for all branches of surgery and medicine.

The Nuffield Department of Plastic Surgery has been given temporary premises in a Nissen hut, with offices for the director (Professor Kilner), the assistant director, the private secretary, a small library, and waiting-room, a small room for photography, and waiting-room for out-patients. So far the hospital has only 14 beds.

'It is expected in the near future', Professor Kilner told me, 'to open at least two wards to accept adult men and women, infants (i.e. those aged one to three) and children, aged three to nine. Until these wards are opened, we must continue our wartime arrangement of operating on Oxford and district cases at the Stoke Mandeville Plastic Centre, by courtesy of the Ministry of Pensions'.

At Stoke Mandeville, 110 beds are used for plastic surgery cases. The unit has had many visitors from abroad, also applications for training from people in the British Commonwealth and foreign countries. A trainee from Chile has been accepted, and is working under the auspices of the British Council; he has the advantage of watching Professor Kilner at work at the Churchill Hospital, Radcliffe Infirmary, Stoke Mandeville, and at Roehampton, and Alton, Hampshire, where work on cleft lip and palate deformities is concentrated.

'The aim of the department', says Professor Kilner, 'is that it should be a real centre for the training of plastic surgeons'.

Close co-operation

Oxford has been chosen because it offers 'magnificent opportunities for close co-operation between the clinical side of treatment and research'; it provides exceptional research facilities, and it is hoped that clinicians in the department will take a keen interest in the research side.

Professor Kilner has given up his London practice and all London hospital appointments to give him more time for these duties. He states, 'I want to carry out experiments, at any rate, in technique. We cannot make any developments here, until we have accommodation for cases. This is one of the subjects in which we cannot divorce the clinical from the research side. I have my own carefully documented and tabulated notes on 1,200 cleft lip and palate cases, each with photographs taken at several stages. I require time to analyse these records and report on my experience'.

The need for plastic surgery treatment is an ever-present one and it is estimated that 100 beds for every two million people are required.

'Industrial accidents have increased steadily in the last generation', Professor Kilner says, 'and, with higher speed in industry and transport, they are bound to become more common. One of the many things we deal with is disfigurement or disabilities caused by disease, or by the eradication of disease by x-ray radium or surgical measures'.

Burns, too, form a very large proportion of the work.

THE FACULTY OF TROPICAL MEDICINE AND HYGIENE, BENGAL

The following students are declared to have passed the D.T.M. Examination, Session 1946-47.

Passed

EXPANSION OF HEALTH SERVICES

DEMOBILIZED MEDICAL PERSONNEL FOR CIVIL EMPLOYMENT
 (From the Press Information Bureau, Government of India, dated 11th May, 1947)

'More doctors, more nurses, more hospitals, more health workers in rural areas—these are some of India's most pressing needs in a major department of nation-building. The existing health services, in spite of their best endeavours, are able to do little more than meet a fraction of the people's needs, owing largely to an insufficiency of personnel'. This was the opinion expressed by a spokesman of the office of Director-General, Indian Medical Service, during the course of an interview.

One source to which health authorities throughout India could with advantage turn was the Army where demobilization was releasing large numbers of trained men for civil employ. Some Army medical officers have had more than five years' commissioned service to their credit, and many have undergone intensive training at Poona and other medical centres in India, besides serving in some of the best equipped military hospitals at home and in other countries.

It was revealed that up to the end of February 1947 3,502 out of a total of 8,590 medical officers had been released, of whom 1,192 have been provided with employment. The figure is small as against the potential demand. The Bhoré Committee has reported that in figures of general mortality India occupies the fifteenth position in a list of 17 countries. New Zealand heads the list and Australia comes second.

In the opinion of the Committee at least 50 per cent of the mortality in the country is preventable. A rapid expansion of the health services is obviously a vital need, and it is felt that local bodies and factory managements can utilize the services of a large number of the medical men already demobilized or to be released in the near future.

THE INDIAN JOURNAL OF RADIOLOGY

OWNED and published as its official organ by the Indian Radiological Association. Joint Editors: Rao Bahadur Dr. P. Rama Rau, Madras, and Dr. K. Manganath Rai, Madras. Price: Single copy Rs. 3/-.

This is a quarterly journal devoted to clinical radiology and allied sciences. The first issue contains a number of interesting articles, all of which are well written and easy to read.

The letterpress leaves nothing to be desired; but, the reproduction of skiagrams is not good. This defect will no doubt be remedied in future issues.

As a first effort all concerned are to be congratulated on a useful publication which should adorn the shelf of every practising radiologist.

BENGAL COUNCIL OF MEDICAL REGISTRATION

(Abstract of the important resolution of the Bengal Council of Medical Registration at their meeting held on the 11th February, 1947)

THE Council adopted a resolution disapproving the Bill for the Registration of Practitioners of Indian System of Medicine in the Calcutta Gazette of 28th November, 1946.

The Council endorsed the proposal of the Madras Medical Council for an amendment of the Indian Medical Council Act so as to provide for a representative of each Provincial Medical Council in that body.

The Council agreed to extend the principle of reciprocity of registration to the Orissa Medical Council, subject to approval by the Provincial Government.

D.D.T. FIGHTS TROPICAL DISEASES SUCCESSFUL CAMPAIGN AGAINST MALARIA

LARGE-SCALE use of D.D.T. and gammexane in the fight against malaria are bringing sensational results in British Guiana, though the work is still only in an experimental stage.

D.D.T. was applied for the first time in a village of 3,000 people in July 1945, and has been repeated twice.

Between 1938 and 1944 the infant mortality rate in the village ranged from 235 to 355 per thousand live births. Approximately 60 per cent of the school children showed evidence of chronic malaria.

Drop in infant mortality

In 1946, the number of births recorded was twice as great as in any of the seven years 1938-1944, and the infant mortality rate dropped to 96. In the last survey only 18 per cent of the school children showed signs of chronic malaria.

Of the colony's population of 376,000 about 266,000 live under conditions of severe endemic malaria. At the end of 1946 an area inhabited by 60,000 people had been brought under control. Plans have been prepared for this year to bring under D.D.T. protection over 80 per cent of the population of the colony at present exposed to the dangers of malaria. The 1947 vote from local revenue for mosquito control is about £35,000.

An expanding campaign is now being conducted for the control of tropical diseases like yellow fever and filariasis throughout the colony. The work is being carried out in collaboration with the Rockefeller

Foundation, the sugar industry and some mining companies.

Sleeping sickness

A Colonial Insecticide Research Team which began work in Uganda (East Africa) in 1945 has successfully dealt with the tsetse fly, the vector of sleeping sickness. Tests were carried out on two small islands in Lake Victoria, solutions of D.D.T. and of gammexane being sprayed over small scattered patches. By repeated applications of the insecticides flies were reduced to a minimum.

Tests against malaria have also been undertaken in Uganda. Solutions of the two insecticides were applied to the internal surfaces of native huts. The experiments confirmed that oil solutions of both D.D.T. and gammexane were effective to an appreciable extent in checking the seasonal rise of malaria.

The Indian Medical Gazette Fifty Years Ago

THE BUILDING COMMISSION FOR CALCUTTA

(Reprinted from the *Indian Medical Gazette*,
Vol. 32, June 1897, p. 222)

THE appointment of a Building Commission is altogether a new departure in the cause of sanitation in India, and one which will commend itself to those interested in the public health of our Indian towns. For though the Building Commission is for Calcutta only, yet there can be little doubt that its deliberations and conclusions will form the basis for consideration and guidance to all municipal authorities in India. The result cannot fail to be far-reaching, and in this respect the benefits to be secured from Sir Alexander Mackenzie's wise action possess more than a local interest.

The Resolution of the Bengal Commission appointing the Commission is as follows :—

'For some years past the Health Officer has pressed upon the Corporation of Calcutta the necessity of amending the Building Regulations in force in the Municipality, in order to make suitable provision for (*inter alia*) fixing the minimum width of public streets, limiting the height of houses in relation to the width of the streets on which they stand, controlling the construction of brick buildings on *bustee* lands, and fixing the minimum size of courtyards within houses, as also the minimum space to be left between the backs of houses for the purpose of ventilation. The subject was discussed at length in the Annual Administration Reports of the Corporation, and the Government Resolutions thereon, cited in the preamble of this Resolution; and the Lieutenant-Governor expressed his views on it in paragraph 19 of the Resolution on the Report for the year 1895-96, to which were annexed extracts from Dr. James's report on the outbreak of plague

in Hong Kong in 1894, bringing out very clearly the intimate connection between defective dwelling houses and spaces and epidemic disease. In that Resolution the Commissioners were informed that if, after considering the subject, they came to the conclusion that a special Building Act for Calcutta is called for in the interests of the health of the city, the Lieutenant-Governor would be prepared to appoint a representative commission to formulate the principles upon which such an Act should be based. Since then the spread of plague in Bombay, Poona and Karachi has given prominence to this aspect of the question, and the report of the sanitary officers deputed by the Medical Board to enquire into the condition of Calcutta, has shown to what an extent overcrowding prevails in Calcutta, and how the construction of buildings in the older part of the town impedes or renders impossible any effective conservancy. In the letter of the 28th December, 1896, the Lieutenant-Governor pressed the Commissioners to come to an early decision on the question put to them in the Government Resolution referred to above, and in their reply they unanimously consented to the appointment of a commission on the understanding that they would make a thorough enquiry into the history and the operation of the existing law and bye-laws on the subject, and would ascertain in what respects these have proved defective, and whether a new Building Act is necessary, or whether the case can be met by amending the existing law. The Lieutenant-Governor generally accepts this view of the functions of the Commission. It has always been his intention that a thorough enquiry should be made into the history and operation of the existing law and bye-laws bearing on this subject, and such an enquiry must necessarily be undertaken before any scheme for fresh legislation can be drawn up.

The task of the Commission will be intricate and difficult. They will have to deal with mixed questions of law, sanitation and engineering, and will further have to consider to what extent the principles recognized in European enactments relating to town buildings require to be modified with reference to the soil, climate and rainfall of Calcutta, the prevailing diseases, and the habits of all classes of the population. For these reasons, and as the proposal to amend the present law has given rise to some apprehensions among the leaders of Native society, the Lieutenant-Governor thinks it desirable that the Commission should be presided over by an officer of judicial experience. The Honourable Mr. Justice Trevelyan, who possesses great knowledge of Calcutta, and has had much experience of the working of the present law, has consented to fill the post of President. His appointment has been approved by the Government of India, and the Honourable the Chief Justice has rendered it possible for him to undertake the work by kindly consenting to

relieve him of Court duties on the days when the Commission sits.

The Lieutenant-Governor is accordingly pleased to appoint the following gentlemen to form the Commission :—

The Hon'ble Mr. Justice Trevelyan	..	President.
The Hon'ble Mr. H. H. Risley, C.I.E.	}	Members.
The Hon'ble Mr. J. G. H. Glass, C.I.E.		
Mr. H. C. Williams		
Mr. A. J. Hughes, C.I.E.		
Babu Kaly Nath Mitter		
Babu Nolin Behari Sircar	}	Secretary.
Surgeon-Captain H. J. Dyson		
Mr. W. Banks-Gwyther		
Mr. F. G. Wigley	

The Commission will be requested to enter upon their labours at once and to report to Government the results of their deliberations within the next six months.

As regards the direction, character and limits of their enquiries, the Lieutenant-Governor desires to give the Commission a perfectly free hand. It is, however, suggested that in addition to the specific points which have from time to time been touched upon in the Health Officer's reports, the Commission might usefully enquire into the desirability of opening out the congested tracts of Calcutta and the most feasible plan of effecting this. They need not, perhaps, unless they themselves find it desirable or necessary, go into the details of any particular scheme of street improvement, but they should examine the general principles on which such operations ought to be conducted in order to make them financially, as well as structurally, successful. It is very important to consider whether the special circumstances of Calcutta point to any amendment or modification of the ordinary Law of Land Acquisition. The issue which lies in fact at the root of the whole enquiry is, to what extent and in what directions private rights may equitably be made to give way to public needs. The Commission also will not fail to consider whether different sets of Building Regulations are not desirable for different quarters of the town, looking to the local circumstances of these areas.

The selection of the Honourable Mr. Justice Trevelyan as President is one which will meet with unqualified approval. He is an old resident of Calcutta and well-acquainted with the habits and wants of the people, while his judicial experience renders him specially qualified to deal with conflicting interests and opinions.

The Commission, we think, is representative and is especially strong on the engineering side. This, with one exception, is as it should be, the exception being that the medical side of the Commission is only represented by one member. Considering that the question dealt with is quite as important from a medical point of view as from the engineering, this omission appears to us to be an important defect which we hope there is yet time to rectify.

LONDON LETTER

(Reprinted from the *Indian Medical Gazette*, Vol. 32, June 1897, p. 228)

IN a former letter I mentioned the formation of the Clinical Research Association, whose purpose is to assist medical practitioners in those special scientific investigations, pathological, bacteriological and clinical, without which, in these days, the practice of medicine is blind and inept. From the second annual report of the Association, which has recently been distributed, it is evident that the scheme has become a great success and supplied a decided want. The list of subscribers is now not far short of 2,500, and they belong to all parts of England, Scotland and Ireland. Membership, for which fee is one guinea, entitles to have work done at considerably lower charges, and to receive bottles and boxes for transmitting specimens, but the Association is open to all, and the terms for the various examinations made, which of course vary considerably according to the nature of them, are very moderate. For example, a member may have phthisical sputum examined for 2s. 6d., diphtheritic membrane for 7s. 6d., urine analysed qualitatively for 3s. 6d., and quantitatively for 5s., a Röntgen photograph taken for 10s. 6d., and material analysed for poison £2 2s.; the same work being done for non-members at 3s. 6d., 10s., 5s., 7s. 6d., 15s., and £3 3s. During the year 1896, 7,227 investigations were made, 1,500 of these were analyses of urine; 908 examinations of diphtheritic membrane; 22,417 of sputum and a large number of specimens of water, milk, and other materials were dealt with chemically and bacteriologically for various purposes. The help which these enquiries must render to medical men who have not the time, the appliances, nor the aptitude to conduct such researches, is of incalculable value, and the standard of practice must be greatly raised by this enterprise.

The report deals with the work of the year in a very instructive fashion commenting on the nature, result, and use of the chemical, microscopic and other processes resorted to, and pointing out difficulties, doubts, advances and desiderata in the light of the present scientific status. It also gives instructions for the selection and transmission of specimens. It is very significant of the value which the profession and public attach to these proceedings that some of the high-class London chemists have organized laboratories in which similar work may be done on reasonable terms. The preparation of serums and animal extracts has also become a substantial branch of the trade. In this line the well-known and enterprising firm, Messrs. Burroughs, Wellcome and Co., are well to the front.

Two deaths have recently taken place in this country which merit prominent notice in the *Indian Medical Gazette*. One is of Surgeon-General James Tyrell Carter Ross, F.R.C.S., which

occurred at Rhyde on the 27th of April. This officer is best known as an energetic and popular secretary of the Bengal Medical Department and editor of the journal during the years 1868 to 1870. Having succeeded him in both these offices, I know well how he put his heart and soul into his work and strove to maintain the honour and efficiency of his department at a time when many influences were in operation to reduce its prestige and limit its usefulness. Ross was born in 1823, and had therefore at the time of his death completed 74 years. He studied medicine in St. George's Hospital School and entered the service in 1845. For the greater part of his career he was employed on the N. W. Frontier. He took part in the Sutlej campaign, and subsequently in the mutiny operation. He was appointed Civil Surgeon of Simla and subsequently selected by Inspector-General of Hospitals J. Murray as his secretary. He drew up some admirable reports of the native army, civil dispensaries, vaccination and lunatic asylums, and strove to infuse a spirit of enthusiasm and energy into the medical executive of all grades. He devoted much time and labour to his editorial duties, and the volumes of this journal which he published present a very interesting view of the events, scientific and administrative, of the time. On his promotion to the rank of Deputy Surgeon-General he volunteered for service and was appointed principal medical officer of the Force that was sent against the Duffla Hill tribes. The remainder of his service was spent in charge of the Saugor circle of medical administration. He retired in 1877, and subsequently proceeded to South Africa for the purpose of superintending nursing arrangement in the Zulu campaign. He obtained the Empress of India Medal in 1877, and was made Companion of the Order of the Indian Empire in 1878. Ross without being a brilliant or talented man was endowed with ambition, energy and common sense, and these qualities, coupled with a high sense of honour and love of his profession and service, rendered his life stirring, useful and productive. Deputy Surgeon-General Henry Vandyke-Carter, M.D. (Lond.), who died of phthisis at Scarborough on the 4th of May *at*. 66, was a great man, and has left an enduring mark on many fields of research. Son of an artist he employed his pencil, as well as his scalpel, microscope and pen to good effect, and behind these gifts of demonstration were the enquiring mind, indefatigable industry, and highly cultivated faculties of observation and reasoning.

He studied in University College, London, and was employed as Demonstrator of Anatomy in St. George's Hospital School before he entered the Bombay Medical Service in January 1868. It was while working at St. George's that he executed those illustrations of Gray's Anatomy, which so many generations of students have found so valuable and helpful. Soon after arrival in India he was appointed

Professor of Anatomy and Physiology in the Grant Medical College and Second Surgeon of the Jamsetjee Jeejeebhoy Hospital. He was also Curator of the College Museum. He subsequently was appointed Civil Surgeon of Satara and Superintendent of the Gaol. In 1872, he took furlough and employed his holiday by visiting Norway, Italy, Greece and other places in order to study leprosy and the disease now known as oriental sore. On his return to India he was deputed to investigate leprosy in Kathiawar, and afterwards to enquire into the nature of the fever which raged during the great famine of 1877-78. He identified it as relapsing fever, and discovered the spirillum which had previously been described by German observers as inhabiting the blood in this disease. This work on spirillum fever is a standard one. He suffered twice from this fever, and was obliged to take sick leave in 1882-83, during which time he devoted himself to literary and scientific work. During the later years of his service, he filled the important office of Principal of the Grant Medical College and First Physician of the J. J. Hospital. He retired in July 1888. In addition to leprosy, Delhi boil and spirillum fever, Carter also worked at mycetoma, lymph serotum, typhoid ulcers, chyluria, 'surra', the malarial parasite, and other pathological subjects. Whatever he did was well done, and his contributions to medical science are good in quality and quantity. On leaving India he endowed a Lectureship in Physiology. He was awarded the Steuart Pathological Prize by the British Medical Association, was appointed Honorary Surgeon to the Queen, and promoted to the rank of Deputy Surgeon-General in 1890. These rewards appear very paltry in view of the distinguished public labours, and eminent services to science wrought by this gifted and most diligent man; but if he did not receive decoration or title, he earned a nobler recompense in the admiration, gratitude and respect which have been, and will continue to be, accorded to his life and work by those who know them best

14th May, 1897.

Current Topics, Etc.

Folic Acid

(From the *Pharmaceutical Journal*, Vol. 157, 31st August, 1946, p. 129)

CERTAIN amount of mystery has somewhat surprisingly developed over the manufacture and use of folic acid. This substance, a constituent of the vitamin B complex and originally prepared from liver, has now been synthesized and its formula elucidated. According to Angier and co-workers (*Science*, 1946, 103, 667), it is a compound of 2-amino-4-hydroxy-6-methyl pteridine and p-aminobenzoylglutamic acid, and its identity with the natural product has been confirmed by a comparison of the ultra-violet light

The vitamin intake in Febrile conditions

The restricted diet associated with febrile illnesses involves a reduced intake of vitamins and minerals at a time when the heightened metabolic rate calls for an increase.

A multiple vitamin and mineral supplement (Complevite) is an essential addition to all such diets.

Supplying the full physiological requirements in this way offers the greatest likelihood of shortening the illness.

COMPLEVITE

The adult daily dose provides:—Vitamin A 4,000 i.u., vitamin B 200 i.u., vitamin C 400 i.u., vitamin D 300 i.u., calcium 153 mg. iron 68 mg., trace minerals 3 p.p.m.

Further particulars concerning Complevite and Fertiol from Martin & Harris Ltd., Mercantile Building, Lall Bazar, Calcutta

Products of Vitamins Limited, London, England.

CONTUSION OF THENAR MUSCLES

A treatment by means of Elastoplast

CASE HISTORY

An iron worker, aged 26, fell against an iron bar which he struck between the thumb and first finger. When examined on the 6th August there was clinical tenderness of the thenar muscles but X-ray showed no fracture or dislocation.

A one-inch wide Elastoplast Plaster was applied, spica fixation.

A fortnight later, there was slight tenderness and another Elastoplast Plaster was applied. On the 10th September

Fig. 1

ber the Elastoplast was removed. There was no tenderness or pain on gripping and the patient was discharged.

The details and illustrations are of an actual case. T. J. Smith & Nephew Ltd., manufacturers of Elastoplast, are privileged to publish this instance, typical of many in which their products have been used with success in the belief that such authentic records will be of general interest.

Fig. 2

In the Elastoplast elastic adhesive Plasters a combination of the particular adhesive spread with the remarkable **STRETCH** and **REGAIN** properties, together provide the correct degree of compression and grip. They mould readily to any part of the body without slipping, rucking, or constriction.

In the treatment of sprains and strains, Elastoplast should be firmly bandaged over

the joint and for some distance above and below. It should be applied as soon after the injury as possible, thus immediately providing firm support and controlling the formation of effusion and hæmatoma.

Elastoplast Plasters available are 1" wide × 1 yd. (1½ yds. when stretched) and 1" wide × 3 yds. (5/6 yds. when stretched). Elastoplast, Elastocrepe, Jelonet and Gypsona are products of T. J. Smith & Nephew Ltd., Hull, England.

Agent: RALPH PAXTON, 10, Lall Bazar, CALCUTTA.

WOMEN AND THE CLIMACTERIC

For thousands of women who undertake heavy tasks through employment—and even in the home—muscular pains, backache and headache are the inevitable results of too-prolonged efforts.

This applies particularly to those subject to dysmenorrhoea and those approaching middle age and the climacteric.

Veganin gives most satisfactory results in such conditions since it is a synergistic association of codeine, acetylsalicylic acid and phenacetin, producing rapid and prolonged relief without ill effects. Veganin is not advertised to the public.

Codeine
Aspirin
Phenac.

ACETARSOL VAGINAL COMPOUND

— BOOTS —

VAGINAL ANTISEPTIC

Acetarsol Vaginal Compound—Boots is a preparation containing acetarsol with boric acid and carbohydrate for local application in the treatment of leucorrhoea associated with *Trichomonas vaginalis*.

Clinical results have shown that Acetarsol Vaginal Compound—Boots is superior to vaginal douches, and the patient is spared much inconvenience on account of the ease with which treatment can be carried out.

Supplied in tablets each containing
4 gr. acetarsol.
Bottles of 25 and 100.

absorption spectra of the two substances—the spectra are identical. Moreover, according to Amill and Wright (*J. Amer. Med. Assoc.*, 1946, **131**, 1201), the infra-red and microscopical appearances of the two crystalline substances are similar. It was at first thought that the liver principle with which folic acid is identical was the factor responsible for the action of liver in controlling pernicious anaemia, but although this is in fact the action of folic acid it is now thought unlikely that the two substances are identical.

Folic acid is given by the mouth, by intramuscular injection, or by intravenous drip. Generally speaking, the American workers have given much larger doses than have British physicians. By the mouth the initial dosage has ranged from 150 mg. to 20 mg., with a maintenance dose of 25 mg. to 10 mg. By injection 150 mg. has been given by intravenous drip, or 75 mg. intramuscularly, the solution being prepared by neutralization with sodium bicarbonate (an equal weight) or with the aid of disodium phosphate, and the solution sterilized by heating in the autoclave at 15 lb. pressure for 15 minutes.

Evidence is accumulating that folic acid has an important place in the treatment of pernicious anaemia. As Amill and Wright point out, since Minot and Murphy introduced liver therapy no other substance, except stomach extract, has produced the marked response now shown by folic acid. Admittedly, the number of patients so far treated is small—supplies are at present exceedingly limited—but those clinicians who have tested the compound are unanimous in reporting favourably on its effects. Wilkinson, Israels and Fletcher, for example, report (*Lancet*, 1946, *ii*, 156) as the result of an investigation at Manchester, that the indications are that 'folic acid can safely be substituted for liver extracts at least in the early stages of treatment of true pernicious anaemia'. The success so far obtained from folic acid will serve as a stimulant to a more intensive search for the true liver principle—it is unlikely that further work will show beyond dispute that in folic acid we have an antianemic factor which cannot be surpassed. Indeed, one case has already been reported where a patient responded to liver extract, but failed to improve under folic acid treatment.

2-Thiouracil in the Treatment of Congestive Heart Failure

By E. P. SHARPEY-SCHAFER

(Abstracted from the *British Medical Journal*, *ii*, 14th December, 1946, p. 838)

'CLINICAL improvement' in patients with severe chronic congestive failure may be defined as a change which shows itself by a fall of venous pressure towards normal levels and an increase in exercise tolerance, which allows the patient to get about or to leave hospital. This definition covers both the high-output and the low-output groups. The data presented in this paper suggest that some cases which have reached a chronic state on ordinary methods of treatment will show 'clinical improvement' when the activity of the thyroid gland is depressed by thiouracil. No benefit can be expected in cases which are becoming rapidly worse, since there is probably little effect on thyroid activity under ten days.

The exact mechanism by which induction of a hypothyroid state results in improvement is still uncertain. It involves the nature of the changes producing 'congestive heart failure'—a subject on which our knowledge is as yet scanty. When the venous filling pressure is lowered by venesection or digitalis in cases of low-output heart failure, the cardiac output increases, and 'clinical improvement' is associated with increased work of the heart. In these cases, however, the oxygen consumption is unchanged as an immediate result of treatment.

Case 1 shows that the work of the heart may not change after thiouracil, and it is probable that some

cases of low-output heart failure may show increased work in the hypothyroid state. In cases treated with thiouracil, although cardiac output may be unaltered, it is maintained at a lower filling pressure and in relation to the oxygen consumption of the individual it is relatively increased.

In cases of heart failure with emphysema it is encouraging that even a few cases can be improved sufficiently to leave hospital.

Regressive Changes in Leprosy under Promin Therapy

By G. L. FITE

and

F. GEMAR

(From the *Southern Medical Journal*, Vol. 39, April 1946, p. 277, as abstracted in the *Tropical Diseases Bulletin*, Vol. 43, August 1946, p. 751)

THIS important paper records the results of the use of promin in the treatment of leprosy over a period of four years. Daily intravenous doses, usually of 5 grammes, have been given over periods of three weeks, with an interval of one week between the courses. In some cases this treatment was continued for more than 4 years with beneficial results in nearly all. Clinical improvement is slow and reduction in the number of lepra bacilli still slower, but progress is nearly always steady, and relapses or febrile exacerbations very rare. Repeated microscopical examinations of the skin lesions showed disappearance of inflammatory signs and diminution in the number of bacilli, but the latter often did not disappear completely, although typical cigar-like packets of organisms became extremely rare. The greatest decline in the number of organisms was seen during the fourth year of treatment, by the end of which they had disappeared from 21 of 42 patients. With one exception the skin lesions showed extensive evidence of atrophy. The deeper foci of infection showed the greatest diminution in size and in the number of bacilli; this may be due to the fact that there is a better blood supply at these sites, which brings the drug into closer contact with the bacilli. The lipoids in the affected tissue remain undiminished, and many vacuolated fatty cells persist. Fibrosis is not a feature of regressive lesions.

The drug appears to act by ridding the blood vessels of lepra bacilli and so preventing their spread throughout the body to form new and progressive lesions. There is little evidence that promin destroys the bacilli in the tissues, but they gradually decrease in the old lesions in accordance with the self-healing tendency of leprosy. This explains the slowly beneficial action of the drug. The absence of acute reactions strongly suggests the destruction of the organisms in the blood and the prevention of their dissemination through the body as the essential action of this treatment, and their gradual reduction in the tissues to the point of final disappearance, as was observed in 10 out of 32 cases treated for four years. A still more powerful bactericidal agent is required for the chemical destruction of bacilli within the tissue cells, and research with drugs of allied composition seems most likely to furnish this requisite.

Leprosy : A New Outlook

By B. MOISER

(Abstracted from the *East African Medical Journal*, Vol. 23, October 1946, p. 295)

ALTHOUGH the disease is a rural, family and home disease, it does not by any means imply direct infection from man to man. Consider the case of bubonic plague. We know that this disease is transmitted from

man to man by the flea of the rat. This fact was discovered by careful research. Is it not possible that Hansen's disease may be transmitted by other similar means, by an intermediary? My own investigations have been with the cockroach, because they are universally present, and because I found acid-fast organisms in them, and not in any other insect examined. It may even prove that the disease is primary in the cockroach, and secondary in man.

The following facts have already been elucidated at Ngomahuru Hospital, S. Rhodesia:—

1. Cockroaches bite man voraciously at night, producing large wounds and scars.

2. These wounds and scars have repeatedly been found to contain the bacillus of Hansen (*Mycobacterium lepræ*).

3. Cockroaches ingest the bacillus of Hansen in great numbers when fed on positive material taken from patients, and the bacilli can be found in the gut of the roach up to the 19th day after feeding. They are sometimes found in such large numbers as to suggest multiplication in the roach.

4. Bacilli can be found unchanged in the dried droppings of the roach for several months, sixteen months being the longest period recorded so far.

5. Twenty-three per cent of roaches caught in the thatched huts of patients in Ngomahuru have been found to contain *M. lepræ*.

6. Five cases are recorded of the presence of acid-fast bacilli, indistinguishable from the bacillus of Hansen in roaches caught in native huts several miles from Ngomahuru, in kraals where no case of leprosy has occurred.

7. In one kraal in Gutu province, from which 9 cases have been admitted at various times, the last being on 5th August, 1940, acid-fast bacilli indistinguishable from *M. lepræ* were found in a roach caught on 18th September, 1945, i.e. 5 years after the occurrence of the last case of the disease in man.

8. Bacilli have been found in the faeces of a series of five roaches, each fed on the powdered dry faeces of its predecessor. How many more can be added to the series is not yet known, but it appears to go on indefinitely, so that it is my contention that it is the faeces of infected cockroaches that are the real source of infection in leprosy.

In about 70 per cent of all cockroaches examined during the last few years, there have been found small acid-fast oval bodies generally a little larger than a red blood corpuscle, but varying in size, which appear to contain acid-fast rods, and it is thought that they may be a stage in the development of Hansen's bacillus in the roach. Occasionally, these oval bodies have been found ruptured, allowing of the escape of the contents, rods or amorphous material. These oval bodies have been observed in man, but not in fleas, bed bugs or ticks. What is their significance? They are a matter for further investigation.

The following six items are reprinted from a Medical Newsletter dated February 1947 released by the International Press and Publications Division of the U.S. Information Service, Washington.

RE-ENFORCING INJECTIONS OF PERTUSSIS VACCINE IN PREVIOUSLY IMMUNIZED KINDERGARTEN CHILDREN

The main object of this study was to evaluate the effect of re-enforcing, or 'booster', injection of pertussis vaccine on kindergarten children who had received their original course of immunization at the Grand Rapids and Michigan City immunization clinics. The immune response of the children was measured by the opsonocytaphagic reaction in 187 children before and after a stimulating injection of plain pertussis vaccine given at the time of entry into kindergarten. Tests before the 'booster' dose suggested that a moderately high level of opsonic activity was maintained for as long as four years after primary immunization, with

the three antigens used. Tests after the 'booster' injection showed reactions on the average 1.6 times those before the injection, and the average increased from the moderate range to that of strong reaction. The results lend experimental support to the policy of giving a 'booster' injection of pertussis vaccine to children just before they start to school when the likelihood of exposure to whooping cough is greatly increased.

(Kendrick, Pearl *et al.*: Re-enforcing or 'Booster' Injection of Pertussis Vaccine in Previously Immunized Children of Kindergarten Age. *Pertussis Field Series V. Am. J. Dis. Child.*, 72, 382, October 1946.)

WATER, SALT AND HEAT EXCHANGES OF MEN IN TROPICAL AND DESERT ENVIRONMENTS

This report is based on comparative field studies of men observed in the California desert and the Florida tropics. The results show that the thermal stress in the desert is about 2 to 3 times greater than in the tropics. A tropical jungle-swamp, however, may exert a stress similar to that of the desert shade. Average 24-hour fluid intakes and sweat outputs were about two times greater in the desert than in the tropics, but the average urinary volume and urinary salt excretion were the same in both environments. Thus men increased their water and salt intakes in proportion to increased losses. Evaporative losses were correlated with solar intensity and dry-bulb temperature, but no correlation could be shown with relative humidity, air movement, or rectal temperature. Clothing diminished evaporative loss by about 100 grams per hour. In the tropics, about 72 per cent of the heat due to work was lost by evaporation, but in the desert all of this heat must be lost by evaporation.

(Molnar, G. W., *et al.*: A Comparative Study of Water, Salt and Heat Exchanges of Men in Tropical and Desert Environments. *Am. J. Hyg.*, 44, 411, November 1946.)

CLINICAL SIGNIFICANCE OF CERTAIN CHANGES IN ELECTROCARDIOGRAM IN ARTERIAL HYPERTENSION

The author analysed 100 selected cases of arterial hypertension and correlated the clinical features with limb lead electrocardiogram in each case. Inversions of T-waves and ST segment depressions in Lead I or in Leads I and II were associated primarily with high diastolic arterial pressure, coronary sclerosis, and hypertrophy of the heart as a whole. These ST-T changes were not significantly related to an increase of thickness of the left ventricular wall relative to that of the right ventricle.

The poor prognosis usually associated with this electrocardiographic pattern was shown to depend largely on other prognostic signs. The pattern of 'left ventricular strain' was not in itself an indication that the myocardium had failed or was about to fail. It was concluded that the preceding duration and severity of cardiac failure are not reflected by the leads. Apparently the degree of left ventricular preponderance cannot be inferred. Finally, the Johns Hopkins investigator says that the likelihood of early death or future cardiac failure cannot be ascertained from the type of electrocardiographic change alone.

(Filley, Giles, F.: The Clinical Significance of Certain Changes in the Limb Lead Electrocardiogram in Arterial Hypertension. *Bull. Johns Hopkins Hosp.*, 79, 261, October 1946.)

STREPTOMYCIN IN THE TREATMENT OF CLINICAL TUBERCULOSIS

This report is based on observations of the effect of antibiotic treatment with streptomycin of 75 cases of tuberculosis. The types of tuberculosis were as follows: miliary, 3 cases; meningitis, 7; pulmonary, 24; ulcerating lesions of upper respiratory tract and large bronchi, 6; cutaneous fistulae of neck, thorax and abdomen, 8; empyema, 7; kidneys and bladder, 14; lupus, 3; bones and joints, 4; and peritonitis, 3. All of the patients with miliary tuberculosis died following temporary improvement. Four of the seven with

meningitis were living and improved at the time of making the report.

Of the 24 cases of pulmonary tuberculosis the lesions appeared to be halted during treatment though three of the patients were unimproved and two deaths occurred in those in whom treatment had been started in a terminal phase of the disease. In the other types of tuberculosis results of streptomycin treatment were not definite or difficult to evaluate. From these studies it was concluded that streptomycin is a therapeutic antibiotic substance highly effective against tuberculosis of experimental animals and is of low toxicity for man.

The results observed are consistent with the hypothesis that streptomycin exerts a suppressive effect on the progress of tuberculous infection in man. Limitations to the intensity of the antibacterial activity and possibly to its duration have been demonstrated. Streptomycin may represent the first clinically feasible antibiotic remedy for tuberculosis, but at this time it cannot be recommended as a substitute for accepted therapeutic procedures, the efficacy of which have been proved by long experience.

(Hinshaw, H. Corsin, *et al.*: Streptomycin in Treatment of Clinical Tuberculosis. *Am. Rev. Tuberc.*, **54**, 191, September 1946.)

THE EFFECT OF ANTICOAGULANTS ON PENICILLIN THERAPY FOR SUBACUTE BACTERIAL ENDOCARDITIS

No statistical, anatomic or histologic evidence could be found that anticoagulants are a necessary adjunct to penicillin therapy of subacute bacterial endocarditis. If the daily dose of penicillin is adequate and treatment is continued long enough, healing of the vegetations will take place as well without as with anticoagulants. The rate of recovery was 100 per cent in our latest 15 consecutive cases, in most of which the patients daily received 1,000,000 units or more. All these patients were treated without the use of anticoagulants.

It is doubtful that anticoagulants prevent major embolism. Fatal hemorrhage resulting from the use of anticoagulants was suggested, although not proved, in two of the cases. The additional cost which is large when heparin is used, as well as the expense and inconvenience to the patient of daily determinations of coagulation or prothrombin time, does not seem justified.

(Priest, Walter S., *et al.*: The Effect of Anticoagulants on the Penicillin Therapy and the Pathologic Lesion of Subacute Bacterial Endocarditis. *New England J. Med.*, **235**, 699, November 1946.)

EFFECT OF INTRACEREBRAL INJECTIONS OF INFLUENZA VIRUSES

It is quite frequently observed that the degree of prostration during and following an attack of influenza in human beings may be out of proportion to the clinical signs observed. Consequently, a series of studies were made, of which this paper is one, to study the toxic properties of the influenza virus in greater detail. Intracerebral injection of preparations of influenza viruses into mice led to tonic and clonic convulsions and death usually within 24 to 72 hours. Histological examination revealed the destruction of the ependymal lining of the ventricles as the dominant finding.

Propagation of the influenza viruses in the central nervous system could not be demonstrated and, in fact, the agents were no longer demonstrable in four days. It was concluded that the observed neurological reactions were the result of toxic activities rather than of virus propagation.

The toxic agents could not be separated from the infectious particles by the use of such techniques as differential high speed centrifugation, absorption onto and elution from chicken red cells and precipitation by protamine. The toxic effect of influenza A virus preparations was specifically neutralized by anti-influenza A and not by anti-influenza B serum and conversely. In addition, antigenic differences were

noted between two strains of influenza A virus by this method of testing.

(Henle, Gertrude and Henle, Werner: Studies on the Toxicity of Influenza Viruses. 1. The Effect of Intracerebral Injection of Influenza Viruses. *J. Exper. Med.*, **84**, 623, 1st December, 1946.)

Nutritional Survey for New Guinea Aborigines

By EDGAR BEE

(Received from Australian High Commissioner's Office, Australia Office, Connaught Place, New Delhi)

WHEN Australian soldiers fought in steaming jungles and on razor-back mountains of New Guinea, their stretcher-bearers in this savage tropic land were aborigines.

The 'fuzzy-wuzzies' as they were affectionately called carried wounded men scores of miles through fever-ridden swamps, along jungle tracks, down precipitous slopes, across swaying catwalks of emergency bridges spanning swift rivers. These primitives—many of them head-hunters not so long ago—showed devotion, astounding gentleness, and care, and such disregard for their own lives, that the Australian people were profoundly moved.

One effort to repay what can be repaid of that still-acknowledged debt to the peoples in the Territory of Papua and New Guinea, is already under way in the shape of a nutritional survey unique in the Pacific region. Responsible authorities are the New Guinea Administration and the Australian Institute of Anatomy, Canberra.

Australian scientists selected for the job are mainly from the Institute, and include two women nutritionists. The women are essential to the success of the expedition, because, among New Guinea primitives there are strict sex taboos regarding preparation and serving of some foods. To get this data will probably be the most formidable task of the expedition. Data on female reproductive history can also be best obtained by women.

The two nutritionists will study in detail, with measurements as far as possible, the food actually cooked and eaten by representative households in each selected village.

The survey will be well based. 'To-day in nutrition we are getting back to the fundamental of food, rather than seeking to isolate and analyse vitamins', says Dr. F. W. Clements, Director of the Institute.

'For this survey our criterion is absolute: how well does the aborigine compare with what we think is his optimum possible condition?'

Fundamental reason for the expedition is the desire of the administration to stimulate local production, so as to introduce more native-grown foods into the ration scale of aborigines, in place of, or to supplement, imported rice. This is a long-term as well as immediate problem.

Before it can be done, the dietary plan of the aborigine in his village must be known. Existing knowledge is scanty.

'We know that he eats certain staples, such as fish, taro, sago, sweet potatoes, but do not know in what quantities', Dr. Clements explains. 'We have to find out exactly what he eats, and how much. From that we can determine what he needs.'

The expedition's aim is to determine the 'nutritional status' of the aborigines. Nutritional status is measured by the general standard of health, physical appearance, mortality rates, the presence or absence of deficiency diseases, and so on. Here again, existing knowledge is limited.

It is known that there is very little beri-beri, but there might be the early stages of deficiency diseases. Aborigines will be examined and laboratory tests will include those of blood and urine. X-ray tests will be made of bones, particularly those of infants, for the degree of mineralization.

A parasitologist will examine debilitated aborigines to determine whether the condition is due to chronic diseases (possibly caused by parasites) or to food deficiencies.

Recommendations will be made on actual dietary patterns. These will be aimed to guide the administration in encouraging the aborigines to grow the things they are missing from their present dietary. Hence the party will have an agriculturist—an administration officer resident in New Guinea and with first-hand experience of agricultural conditions there.

Comparative nutrition surveys will be conducted on five or six groups, eating different staples—such as fish, taro, sago.

One village has been definitely selected—Busama, between Lae and Salamaua in New Guinea. Another village will be within the region of the road to Wau up the Markham Valley. A third will be a fishing village in the Trobriand Islands.

The war has had both good and bad effects on the aborigines. One benefit has been the introduction of beans and peanuts into areas where they had never before been grown. Also, the use of corn is spreading, and contacts have widened.

'But some of the inhabitants are pretty badly off as a result of the war', says Dr. Clements. 'Both Japanese and our soldiers—often under the spur of hunger—pillaged their gardens. This happened particularly around Lae, and in other places. Most of the gardens were put back into condition within a year of the war's end, provided seed was available. The aborigines depend on last year's crop for this year's seeding. I understand that in most areas the gardens are fairly well established again.'

'Cocconut palms were heavy sufferers in many areas, and will take time to regrow. But cocoanuts are not a prominent article of diet except amongst the sago-eating people, for whom cocoanuts form about 25 per cent of the diet.'

Perhaps the most serious war-caused shortage in village food supplies is live stock—in effect, pigs.

Sea, land and air transport will be used by the party. A schooner will probably land members and equipment on a beach near Lae. There will be motor transport in the Markham Valley for part of the way up the Wau road, and after that again, probably, the aborigine bearer will be necessary. A plane may be used to carry party and gear to an aerodrome somewhere near a village in the mountain districts.

'We will have one of the best-equipped field laboratories anywhere', says Dr. Clements. 'We have arranged for a generating power unit, an x-ray plant and a certain amount of electrical laboratory equipment.'

Trained aborigines will assist the party. On previous research work in the area, Dr. Clements used aborigines trained at the School of Tropical Medicine, Sydney. Two groups of about 12 Papuans each were trained there in 1934-35.

The survey, which is being financed through the Department of External Territories, is being done virtually for the New Guinea Administration by, and at the suggestion of, the Institute of Anatomy—the body in Australia equipped for this type of work. The Institute in the past has advised the administration on ration scales.

There have been not more than four or five such expeditions anywhere in the world to date. A survey was made in Nyasaland Protectorate, South Africa, in 1938, under the aegis of the Medical Council of Great Britain, led by Dr. B. S. Platt, Professor of Human Nutrition, University College, London. Dr. Platt is now engaged on another nutritional survey in Gambia on the north-west coast of Africa.

The Rockefeller Foundation conducted a similar survey under Dr. R. S. Harris among the desert natives of Mexico.

In China and India there have been nutrition surveys, but not among undeveloped primitive peoples.

However, nutrition is attracting increasing attention and larger allocations of funds. One might mention,

for example, the important Inst. Nacional Nutricion, Buenos Aires; also the Institute of Medical Research in Johannesburg, South Africa, which has done a lot of work among aborigines in hospital in gold mining areas.

The Australian party will be away about six months—for all the dry season in New Guinea—returning to Australia in August or September.

A party will have to return to New Guinea to do some work in the wet season.

Northern Territory Survey

The Institute is not confining its nutritional surveys to aboriginal peoples. A survey of the European people of the 500,000 square mile, almost empty Northern Territory of Australia, with some attention to aborigines also, will be undertaken by a party of three women nutritionists and a male biochemist.

Equipment will be kept down to a minimum, as the party will have to rely almost entirely on planes for transport. Medical officers of the Commonwealth Public Service stationed throughout the territory will assist them.

Food consumption of territorian housewives will be studied especially. Data will be collected on food costs, an important factor, as many foods have to be brought into the area by air, owing to vast distances in this land where average population density is only one person to every 100 square miles, and where, in monsoonal regions, land transport may be dislocated for weeks by heavy rains.

An important part of the task of the biochemist will be to estimate the vitamin C content of the blood of infants, children and pregnant women.

This survey is designed to assist the Federal Government to populate the northern half of Australia. Nothing like it has ever been attempted before in these lonely regions.

They Sweat it Out for Science

Professor Lee, Australian Physiologist, put animals, birds and humans through their paces to see how they react in conditions of extreme heat and humidity

By LARY BOYS

Canberra

(Received from Australian High Commissioner's Office, Australia Office, Connaught Place, New Delhi)

In Brisbane, capital city of Australia's sub-tropical State of Queensland, medical students and university professors work through their vacations to find out how heat and humidity affect working efficiency of humans and animals.

In charge of the experiments is energetic Dr. D. K. Lee, Professor of Physiology at Brisbane University. He first became interested in climatology at the University College, London, in 1934, and continued his research at Singapore in 1936.

The present organization began in 1937 within the Department of Physiology at Brisbane. Laboratory studies of men and animals have continued to the present time.

From 1942 to 1945, various investigations were carried out in North Queensland and New Guinea for the armed forces. During this period the nature and incidence of 'tropical fatigue' were thoroughly studied and as a result much valuable advice was made available to the Allied Forces serving in the steamy jungles north of Australia.

In a specially built laboratory overlooking the Brisbane River, Professor Lee and his assistants work through the long summer vacation when Brisbane's heat and humidity are at their peak. Human subjects, all volunteer medical students, do various kinds of work and exercise outside in the sub-tropical sunlight. Or they go into sealed chambers where any climatic conditions of heat or humidity can be reproduced by a special conditioning plant.

Sweat losses, respiratory and pulse changes are faithfully recorded by special instruments for each subject under observation, man, sheep, or domestic fowl.

Investigations carried out are prompted by practical considerations of tropical settlement, although a definite attempt is made to keep the long-range fundamental scientific requirements in mind. On the human side, attention is given to the reactions of man to various types of hot atmospheres, and the effects of clothing and housing upon his welfare in such climates.

The workers also have well in mind industrial conditions, as a result of which men spend long periods in 'tropical' weather.

As domestic animals play an important rôle in the economy of tropical habitation, their reactions are studied with particular interest. The way in which animals react, the methods of selecting those most suitable to tropical conditions, and changes made by hot climates are investigated. Information is gradually accumulating on the wider scientific problem of how animals adjust themselves to hot climates.

Interesting point confirmed by Professor Lee's department during the war was that Australian soldiers who had been born and reared in tropical Queensland perspired more 'economically' than soldiers from the more temperate parts of Australia and were less likely to be distressed by excessive heat and humidity than their fellow-countrymen from the colder South. This was despite the fact that in all cases, the soldiers examined came from the same ancestral stock—predominantly British.

Professor Lee's laboratory maintains close liaison with the Medical Research Council of Great Britain, the National Research Council of America, the American Society of Heating and Ventilation Engineers, and the Food and Agriculture Organization of the United Nations.

Professor Lee has been granted leave of absence from his duties at the University to spend the next 12 months in America. He has been invited by Dr. Isaiah Bowman, president of the John Hopkins University, to join with his staff in studies of a tropical settlement. On 18th May, Professor Lee will deliver a paper, 'Effects of heat on dairy cattle' to the American Physiological Society at Chicago.

During his stay in the United States he will do a survey of animal climatology for the Food and Agriculture Organization of the United Nations.

On his return to Australia next year, Professor Lee will resume control of Brisbane University's experiments in climatological physiology, which will continue uninterrupted during his absence.

New Approach to Health Problems

United Nations' Plans to Control Disease

By S. GORDON COLLIER

AMONG the most propitious conferences which the United Nations have yet held is that of the Interim Commission of the World Health Organization, which has recently been discussing in Geneva some of the projects which will be laid before the World Health Assembly. This Assembly is to be held within six months of the date on which 26 members of the United Nations have joined the World Health Organization and thus established it as a permanent agency.

In preparation for this general conference on health, the procedure which has proved successful in trade and other questions was followed and a preliminary conference, or Interim Commission, of 18 nations has therefore been meeting at least every four months to examine plans for the conference. The place and date of the world conference is one of the items on the agenda, the others being details of projects to be discussed at the world conference later.

First Common Interest

The world health talks have begun well, and that for three principal reasons.

In the first place, the conquest of disease was probably the first of their common interests in which the nations realized that they had nothing to lose, and everything to gain, by whole-hearted co-operation. In the second place, and for this reason, the United Nations were able to take over from the League of Nations an excellently organized health department which, though little publicized, had a long record of solid achievement behind it. And, finally, the Interim Commission is nursing the new-born baby of world co-operation with great care, teaching it to walk first through relatively simple problems, before it starts running into highly controversial or revolutionary projects.

It is a good augury, therefore, that the agenda at Geneva makes good reading for the student rather than headline news for the public.

The ultimate basis of public health administration, both nationally and internationally, are the records of sickness upon which expenditure and other plans are based. Certain aspects of these records therefore figured high on the agenda of the Geneva Conference, and notably the standardization of names for the causes of death and disease. The League of Nations made great progress towards such standards of nomenclature, and it was this which made it possible for health organizations throughout the world to get the detailed statistical summaries published by the League before the second world war. A world conference is scheduled to take place on this subject in Paris next year, and it is hoped then to carry this matter a step further.

Standardization of Records

In Britain, for instance, standardization of all kinds of sickness records has led to a unique experiment by the Bureau of Health and Sickness Records at Oxford, which is collecting all the available information about every type of sickness—not just fatal illness and notifiable diseases—in a large part of the country. Limited records have been kept for many years by various organizations, but these have either concerned all illness in a relatively small area (e.g. London, Glasgow, the New York Department of Hospitals scheme, similar local schemes in Canada, etc.), or they have been restricted to particular diseases (e.g. the records of the Birmingham Tuberculosis Department, the United States Public Health Service records of venereal disease, morbidity, etc.).

The aim of this British experiment is to tabulate all known facts about sickness in a large area covering both industrial and rural communities, and from many different independent sources, so that a far more complete picture of public health may be made available in which important new facts about the effects of different environments may be discovered.

For several years now, machines have been tabulating this information at the rate of 12,000 cards every hour, checking, counting and finally sorting them according to common facts they contain. This is the type of analysis which can only be applied internationally when the names of sicknesses have been standardized, and the progress of the Geneva Conference on this subject may well have results of much more far-reaching importance.

New Treatments

It is the treatment of disease, rather than its tabulation, however, which is the primary aim of a health service, and one of the biggest problems in this field which has had to be faced in Geneva arises from the discovery, during and shortly before the war, of revolutionary new treatments for many of the most widespread diseases.

Drugs only known to medical practitioners for a few years are now being made either under various names, or to different formulæ, or both, in many countries, and scientific literature announcing important developments in one country may therefore be either incomprehensible or inapplicable in others. Consequently, a sub-committee on biological standardization was also set up, and its work has enabled the Geneva

Conference to carry the standardization of biological and pharmaceutical products throughout the world a stage further.

Doctors in Chile, for example, where the pneumonia death-rate before the war reached 485 per 100,000 inhabitants, in Egypt where it was 317, or in Spain where it was 166, will all be better able to obtain the preparations of sulphapyridine and sulphathiazole proved most effective against this disease in Britain, where these drugs were developed.

Similarly, British developments in the use of penicillin can then be followed exactly throughout the world, just as tropical countries will be able to benefit more directly from Britain's development of the diamidine drugs for treating sleeping-sickness, kala-azar and leishmaniasis. The standardization of these medicines would undoubtedly be one of the most important steps yet taken in the world conquest of disease.

Positive Approach

Even more important than the treatment of illness, however, is its prevention, and here again the health commission has undertaken important work in reviewing the administration and revision of international sanitary conventions. Now regarded in Britain, where it was developed, as a science in its own right, sanitation has not only prevented the spread of epidemics from country to country, but has been the chief means of fostering among the peoples the new positive approach to health.

This approach is the cornerstone of Britain's own National Health Service as it is now being planned and, as new discoveries help to diminish sickness in other countries during coming years, the view that good health is a gift to be sought and developed, and not merely maintained, may well spread throughout the world.

The Care of Patients with Severe Asthmatic Attacks

By C. SUTHERLAND

(Abstracted from the *Medical Journal of Australia*, Vol. II, 13th July, 1946, p. 51)

TREATMENT

BEFORE treatment is decided on every possible means must be taken to define the factors leading to the attack to assess their relative importance and to deal with them. Results will be poor if adrenaline is poured into a dust sensitive patient who is allowed to remain in a dusty bedroom or if a child sensitive to foods or to products of intestinal fermentation is allowed to remain with a full bowel.

ADRENALINE

Mild attacks of asthma are generally relieved for several hours by the subcutaneous injection of three to five minims of adrenaline (1 in 1,000 solution). Some patients require more and those who have used adrenaline for years may need seven to ten minims or more every twenty to thirty minutes before an attack is controlled. The intelligent patient can usually give useful guidance about 'how much' or 'how often'. One should aim at using the smallest dose which will give complete relief for a few hours and for the average adult with a moderately severe attack ten minims (0.6 millilitre) is usually adequate. But it must be realized that the optimum dose for any one patient must be found by experiment.

Severe asthma may persist for days and if effective measures are not taken to relieve the bronchiolar spasm further mechanical complications such as congestion in the lung ensue adrenaline becomes less effective and the patient becomes dangerously exhausted. A few adequate doses early in an attack are much more helpful than much larger doses later on.

When one realizes that one is dealing with a stubborn attack in an adult it is as well to fill a two-millilitre

syringe with adrenaline (1 : 1,000 solution) and after consulting the patient if he is an intelligent 'oldhand' inject a suitable dose (say ten minims) then place the syringe horizontally in a sterile test tube beside the bed and wait ten minutes. If there is no sign of relief give another ten minims and repeat the dose every fifteen or twenty minutes until the attack is controlled. Overdosage is indicated by pallor, tremor and tachycardia and a feeling of general discomfort and of course these symptoms are indications not to give more for an hour or so. Tremor is perhaps the most reliable sign and is best elicited by balancing a sheet of note paper on the patient's outstretched hand. The patient's condition is indeed serious if these signs of intolerance appear before the bronchiolar spasm is relieved.

It is at this stage morphine is so dangerous and if it is given before the spasm is controlled there is great danger that the patient will cease to struggle and will lapse into unconsciousness from which he does not recover. Given early in an attack to a vigorous patient a small dose is not quite so dangerous; but those who see large numbers of severely asthmatic patients are unanimous in emphasizing the dangers of sedatives of this type.

Once spasm has been controlled to a certain extent one should see that it is not allowed to return and the optimum dose should be injected as often as necessary immediately any hint of an increase in wheezing is heard. A good plan is to leave a stethoscope with the patient and the attending nurse can soon recognize the prolonged expiratory wheeze which indicates the return of bronchiolar spasm. Some physicians leave the needle in one spot and inject one minim of adrenaline per minute. The disadvantage is that intense constriction of blood vessels occurs at the site of injection and little absorption takes place after the first few minutes.

Care must be taken not to inject adrenaline into a vein. Select an area where large veins do not occur and look carefully so that small veins also are avoided. After inserting the needle pull back on the plunger. If blood appears in the syringe withdraw the needle and try another spot. If the patient is in his own home he should be taught how to inject adrenaline (into his thigh) as in many attacks repeated small doses will be necessary.

Adrenaline may also be used by inhalation but a 1 : 100 or even 1 : 10 solution may be necessary. A spray or nebulizer is unsuitable and only a specially designed glass vaporizer giving a very fine mist must be used. Some vaporizers are badly made or the jets become blocked so that if the patient gets no relief these mechanical defects must be thought of. Great care must be taken not to inject these strong solutions of adrenaline subcutaneously in error.

It sometimes happens that patients who have had frequent injections of adrenaline become temporarily intolerant so that further doses make them worse. In such cases it is better to stop using adrenaline for twelve or twenty-four hours and to rely for a while on other remedies, especially 'Aminophylline' and oxygen. As a rule it will be found after a spell of twenty-four hours that the adrenaline is again beneficial.

A patient can be overdosed with adrenaline; but by far the commonest error is for doses to be too small and too infrequent. It is a technique to order a fixed dose of adrenaline at fixed intervals; find the optimum dose and inject it as often as necessary. This may mean an injection every hour or oftener. A patient should not be allowed to remain wheezing or obviously short of breath unless signs of intolerance of adrenaline have appeared.

The absorption of adrenaline is prolonged when it is administered in an oily medium such as peanut oil and it is sometimes more convenient to give it in this slowly acting form especially at bedtime to ensure an undisturbed night.

'AMINOPHYLLINE'

'Aminophylline' (also called 'Cardophyllin' or 'Euphyllin') is a mixture of theophylline with ethylene diamine. It is said to cause lowering of venous and

intrathecal pressure, dilatation of the coronary arteries, stimulation of respiration, an increase in the volume of blood flowing through the lungs and bronchial relaxation.

It was originally given intravenously but most authorities now prefer to give it rectally. Barach recommends injecting 0.6 gramme (0.5 gramme for small patients and 0.7 gramme for large patients) dissolved in 20 millilitres of warm water into the rectum through a soft rubber catheter, and this dose should be given twice a day for five days and then once at night for three weeks so that prolonged relaxation is established. The attack may subside after the first few doses but the full course should be given in order to produce a lasting effect. When the drug is given intravenously 0.48 gramme is dissolved in 20 millilitres of 10 per cent glucose solution and injected slowly at least eight minutes being taken. 'Aminophylline' is an irritant and must not be given intramuscularly.

OXYGEN

In the administration of oxygen, linen tents and funnels are, of course, useless, and oxygen must be given with a well-fitting mask (for example, 'B.L.B.') or through a nasal catheter (the gas should be moistened) or in a 'cellophane' tent. Give at least four to eight litres per minute if necessary for hours at a stretch. In the United States of America a mixture of 80 per cent helium with 20 per cent oxygen is found to be most effective, but it is not available in most countries. A mixture of oxygen with 5 per cent carbon dioxide is sometimes useful as an expectorant, but generally pure oxygen gives more relief.

PURGATION

The value of purgation should never be forgotten. Some stubborn attacks persist until the bowels are well opened. Probably calomel (four grains) followed by Epsom salt next morning is most effective. Bowel wash-outs are also frequently of great benefit; but if they are to be effective, the bowel should be gently washed until the return is clear with large volumes of warm tap-water or saline solution, with the aid of a funnel, a yard of tubing and a soft catheter inserted a couple of inches into the rectum.

VENESECTION

To plethoric subjects with circulatory embarrassment venesection is often of dramatic benefit. Of course, it is useless and harmful for dehydrated subjects.

ANÆSTHESIA

Asthma sometimes disappears for months after a major operation, and inhaled ether is sometimes used in stopping attacks. The patient tends to become more distressed until consciousness is lost, but the asthma disappears when full anaesthesia is reached. Generally, it is preferable to give ether rectally (two ounces in four ounces of olive oil). Urbach recommends that equal volumes of ether and olive oil should be whisked for several minutes with an egg-beater. Five to seven ounces of this golden-brown fluid are then injected rectally.

'Avertin' (60 milligrammes per kilogram) is also given rectally; the usual solvent is amylene hydrate, but, according to Coke, the drug may also be dissolved in 120 millilitres of cold distilled water. But 'Avertin' is a respiratory depressant, and as a rule, ether is preferable.

PARALDEHYDE

Two to four drachms or more of paraldehyde in four ounces of olive oil may be given into the rectum. This is often a most satisfactory remedy. Often this dose must be repeated in twelve hours.

ASPIRIN

A proportion of asthmatic patients are intolerant of aspirin, and by those it must be carefully avoided. To

most of the remainder it is beneficial, and it is well worth a trial even in desperate cases.

COCAINE

Cocaine should be avoided, as addiction can easily follow repeated use. But in desperate cases a cautiously used cocaine spray (5 per cent for the nose) or application of cocaine to the nasal mucosa is sometimes dramatically helpful. Proprietary sprays for inhalation formerly contained traces of cocaine with adrenaline and papaverine.

MORPHINE, HEROIN, ET CETERA

Given early in an attack when the patient is vigorous morphine, heroin and similar drugs are often helpful; but they must never be given when the patient's condition is causing concern, as death can easily occur after even small doses. . . . Itals they should not be given except . . . of the honorary physician or medical superintendent. Pethidine seems useful but is still under trial. Orally, an initial dose of 25 to 100 milligrammes is recommended and then 25 to 75 milligrammes two or three times a day.

IODIDES

Ten grains of potassium or sodium iodide three or four times a day should be tried in all chronic cases; but intolerance of iodides is common. As a rule it is preferable to give iodides in a simple mixture without lobelia or stramonium, which tend to upset the digestion if given for many days.

SULPHONAMIDES, PENICILLIN AND 'NOVARSENOBILLON'

Sulphonamides are sometimes helpful even when no obvious infection is present and these or penicillin are most useful when infective bronchitis and some fever have occurred. Arsenicals administered by the intravenous route occasionally succeed brilliantly especially in eosinophilic infiltration of the lung.

EPHEDRINE

Ephedrine given orally is useful in mild attacks but should not be used in severe attacks. It may produce insomnia, tremor and palpitation and these unpleasant effects are lessened to some extent if it is combined with a sedative such as phenobarbital or 'Amytal'. It can produce toxic effects and in the writer's opinion it should not be given subcutaneously.

POSTURE AND ENVIRONMENT

In a severe attack the patient should have a good pile of firm pillows or he should sit in a comfortable chair until the attack subsides. Often the patient is better on a balcony or verandah. When allergy is a factor kapok and feather pillows must be avoided and dust must be reduced to a minimum or better still the patient should be moved into hospital until the attacks subside.

DIET

Allergy to foods does not seem to be a common cause of *status asthmaticus* but many patients seem to recover more rapidly if they avoid milk and eggs for a few days. On the other hand the patient has a strenuous time during a prolonged attack and should take fruit drinks, sweetened barley water and tea when he can. If it is known that milk makes no difference he should have milk in moderate quantities and when the attacks have lessened he should have a plain well-balanced and adequate diet.

OTHER REMEDIES

Autohaemotherapy, lumbar puncture, the intravenous administration of calcium (10 millilitres of a 10 per cent calcium gluconate or calcium chloride solution) and the intravenous administration of glucose or sucrose have all been used; but it is difficult to say whether they have much real effect. Adrenaline oxygen and 'Aminophylline' are at present the only really satisfactory remedies and one must cultivate the art of using them.

The Rh Factor in Feeble-Mindedness and Other Diseases

By L. H. SNYDER

(From the *Minnesota Medicine*, Vol. 29, February 1946, p. 121, as abstracted in the *International Medical Digest*, Vol. 48, June 1946, p. 360)

'IN recent years much attention has been devoted to the study of the inheritance of various traits both normal and abnormal in human beings. Perhaps the most fascinating of these traits are the recently discovered Rh blood types. At first apparently of only theoretical and academic interest the Rh factors have become of importance in legal medicine in transfusions and in the study of infant mortality and are now extending their influence into the fields of psychology and psychiatry.'

'There are no normal antibodies against antigen Rh in human sera. . . . Rh is highly antigenic to human beings. Repeated injection of Rh+ blood into an Rh- person results in immunization of the recipient and transfusion reactions of increasing severity. It is essential therefore to transfuse Rh- blood into an Rh- person. For even though the first transfusion might cause no reaction the immunization process would be initiated and subsequent transfusion might be fatal.'

The Rh antigen has been shown to be the primary cause of erythroblastosis foetalis. 'In nearly all cases of the disease the mother proved to be Rh- the foetus Rh+. The Rh antigen in the foetus was of course inherited from the father. The Rh- mothers can be shown to have developed antibodies against Rh. Apparently the Rh antigen has passed through the placenta into the circulation of the mother, immunized the mother and the maternal immune antibody has then passed back into the foetus damaging the red blood cells. The result is hæmolytic jaundice and other effects. While the test tube reaction is agglutination the end result in the foetal circulation is hæmolysis. The regenerative activity of the foetal blood-forming system floods the circulation with immature red cells (erythroblasts) hence the name erythroblastosis. Ordinarily the first Rh+ child born to an Rh- mother is itself unaffected. A second Rh+ embryo, however, stimulates the further rapid production of antibodies and this and all subsequent Rh+ foetuses will be affected. Of course if an Rh- woman has received a transfusion of Rh+ blood previous to her first pregnancy she will already have been immunized and the first Rh+ foetus she carries can be affected by the antibodies. Some women produce antibodies so slowly that several Rh+ foetuses may be required before one becomes erythroblastotic.'

Using the three antisera eight kinds of people may be distinguished as follows: Rh^o, Rh', Rh'', Rh^o Rh', Rh^o Rh'', and Rh-. The first seven of these eight types are Rh+ for one or more of the Rh antigens; the last one is Rh negative. Using all the Rh factors 87 per cent of American whites are Rh+ and only 13 per cent are Rh-.

One should expect to find erythroblastosis then in 8.32 per cent of all births, that is, about 1 in 12. 'However, the frequency of clinically diagnosed cases has never approached this figure. The recorded incidence is about one-half of 1 per cent; or about 1 in 200 births.'

'The cases of erythroblastosis are not distributed at random among the potential Rh- mothers but usually occur several in the family. It may be, then, that only some women are capable of producing potent antibodies against the Rh antigens. It may also be true that the antigen gets through the placenta only in some Rh- mothers.'

The writer has been investigating the blood of the undifferentiated feeble-minded at the Ohio Institution for the feeble-minded and of their mothers. 'The complete results up to date are as follows: Of 169 mothers of feeble-minded children 38 are Rh-, whereas only 21 or 22 would be expected. This difference is statistically highly significant.' Of 171 feeble-minded

children, 27 are Rh+ from Rh- mothers whereas one should expect only 14. This deviation is also highly significant when tested statistically.

Thus it would seem that in some instances the immune antibodies of the mother produce effects on the brain tissue instead of the usual effects recognized as erythroblastosis. It has been suggested that the immediate effect of red cell destruction is anoxia, and that this lack of oxygen, if it occurs at a time when the brain of the embryo is in a critical stage of development, may very well cause permanent mental deficiency.

Thus the gap between the calculated incidence of effects of Rh immunization and the observed incidence has been partially closed up. At first glance it might appear that the death of erythroblastotic infants is gradually eliminating the Rh factor. Actually it is the other way around, and the Rh factor is being eliminated instead. This is due to the fact that every erythroblastotic infant is heterozygous, Rhrh, so that each death removes equal numbers of the two genes. Since there are far more Rh genes than rh genes in the world, a larger proportion of the rh genes is lost each time.

'The feeble-mindedness due to Rh incompatibility is an acquired mental deficiency, and cannot of course be transmitted to offspring. It could thus account for some of the isolated cases of undifferentiated feeble-mindedness in otherwise highly intelligent families, and also for some of the instances where two feeble-minded parents have produced normal offspring. Perhaps not more than 10 per cent of all undifferentiated mental deficiency can be attributed to Rh incompatibility. It would seem advisable that every girl, on entering into marriage, should learn her Rh type and that of her husband. If she is Rh- and marries an Rh+ man, she should inform her family physician of this fact, so that he may take all available precautions for the preservation of any Rh+ infant she might have. Once in a great while an Rh- mother has an erythroblastotic child. The danger is very small indeed, but the hopes aroused by this discovery are great. In these cases the effect is that of the Hr factor. The Hr factor is reciprocally related to the Rh factor. Corresponding to the three Rh antigens, Rh^o, Rh' and Rh'', three Hr antigens, Hr^o, Hr' and Hr'' are postulated. Two of these, Hr' and Hr'' have been discovered and described; the third will no doubt soon be found.'

'The rare cases of an erythroblastotic child born to an Rh+ mother are cases where the mother is Hr- and the child is Hr+. The Hr- mother and the Hr+ child must both be Rh+, since . . . an Hr- mother cannot be heterozygous for rh. The father may be of any Rh type, since Hr+ individuals occur in all Rh blood types.'

The hopes aroused by this new discovery are that by the use of anti-Hr serums one may be able to pick out, in some instances, at least heterozygous Rh+ men.

Using antigen Hr', there are 10 kinds of Rh types instead of 8. There would thus be 3,200 different types classifiable. Using all three Hr antigens when they become available, there will be 18 Rh types, and thus 5,760 blood types altogether.

Relapsing Fever in an Eight-Day-Old Infant

By W. A. YOUNG, *et al.*

(Abstracted from the *East African Medical Journal*, Vol. 23, November 1946, p. 345)

IN March 1945, an African mother was admitted to hospital as a maternity case. Her clothes were removed and she is said to have bathed before donning hospital clothing and being accommodated in the Maternity Block, the newest part of the hospital. The baby was born the same afternoon, perfectly fit, but on the eighth day became feverish. Examination of its blood revealed heavy infection with *Treponema duttoni*. Repeated examinations of the blood of both mother

and baby were undertaken, always with the same results: Mother negative, child heavy *Treponema duttoni*. Most careful search was instituted for *O. moubata*, and none could be found, nor ever had been found in the hospital, and it was difficult to believe that the Maternity Block could afford harbourage for this tick. Visitors are allowed into the wards daily; the mother had been allowed out of bed for the first time since her admission on the third day after delivery; the child had lain from birth in a wooden cot in a room by itself away from the mother and visitors.

The father was called in and proved to have no *Treponema duttoni* in his blood, but he showed a faintly positive Kahn. He said that neither he nor his wife had had fever, but that they had slept in a tick-infested house on their way to hospital.

Despite immediate institution of treatment, the child died.

Clinical and Pharmacological Aspects of the Toxicity of Streptomycin

By D. G. MADIGAN, *et al.*

(Abstracted from the *Lancet*, i, 4th January, 1947, p. 9)

IN the course of the evaluation of antituberculous chemotherapeutic drugs in this hospital the opportunity to evaluate the status of streptomycin in a side-by-side comparison with established sulphone chemotherapy presented itself in June 1946. A limited supply was available from one source (w.f.) in the form of seventeen batches which had been subject to pharmacological control. The material was available in sterile rubber-capped containers, in the form of a freeze-dried powder and contained the equivalent of 0.2 g. of pure streptomycin base, together with a supply of sterile pyrogen-free distilled water. The biological control of the material before it reached us included tests for sterility and freedom from pyrogens, freedom from histamine-like impurities, and with one exception, from antidiuretic substances. The average lethal doses in an acute experiment for mice of these batches were less than that of pure streptomycin. On the occasion of intrathecal injection an additional toxicity test was made on the batches used for this purpose. However, the figures obtained subsequently proved to be average values for all batches, an isotonic solution being obtained when one container (0.2 g.) was dissolved in 18 ml. of distilled water. In practice one container was mixed with 2 ml. of distilled water, but even with such a hypertonic solution no acute toxic effects were encountered. The usual precautions were taken of withdrawing at least an equal volume of cerebrospinal fluid, the use of a narrow-bore lumbar-puncture needle, very slow injection, and subsequently raising the foot of the bed.
